of civil and criminal jurisdiction are regularly held in each county, and while the judges are often selected for larger districts the administrative officers of the courts are county officers. In some states there are distinct county courts, and in most states the county is the district for probate administration and the public record of land titles. In connection with these and other functions courthouses and jails are maintained. In most states finance administration is an important function of county government. In the states of the South and far West and to an increasing extent in other states the assessment of property for state and local taxes and the collection of such taxes is carried on by county officers. The county is also an important district for election purposes. Not only county officers but in most states members of the state legislature are elected by counties, and the county is the district for conducting the elections and canvassing the returns for county, state and national officials. The position of the county as an election district is reflected in the importance of the county committee in party organizations. The county ordinarily has important functions in the construction and maintenance of roads and bridges and sometimes of drainage and other public works, including in some states water supply, sewers and lighting plants. It is the usual district for the administration of poor relief, maintaining a poor farm or almshouse. Generally there is a county school officer, and in many of the southern and western states the county is the primary unit for local school administration. In these lines there has been a distinct tendency toward an increase of state activity and control. On the other hand, the scope of local county functions has increased through the development of county hospitals, county libraries, county parks and airports and new activities in matters of public health and social welfare. County revenues and expenditures per capita have doubled in each decade since 1900 and during recent years they have increased at a faster rate than city finances.

The importance of the county varies considerably in different sections of the country. The traditional classification has been based on the situation in the colonial period, in which the county ranked as of first importance in the South, of least importance in New England, while in the middle group of colonies it occupied an intermediate position. Based on an enumeration of functions and the relative importance of counties and towns, this arrangement continues,

with the far western states grouped with those of the South. But if the scope of county activities is measured in terms of per capita expenditure, the county is of much the greatest importance in the states of the far West. Second place is taken by the north central and middle Atlantic states, with the southern states third and the New England states last.

In the machinery of county government the most significant feature is the lack of any definite system of organization. About two thirds of the state constitutions have provisions for the election of a list of county officers, and in nearly all the states there are a number of elective county officials, largely independent of each other, with no concentrated executive control and no adequate representative council with substantial powers of local legislation. The doctrine of separation of powers is largely ignored.

In all but two states (Rhode Island and Georgia) there is in each county an elective county board which usually levies county taxes, has control over some matters of local administration and has a limited supervision over other elective officials. In three fourths of the states the county boards are small bodies of from three to ten members. In most cases these small boards are elected at large and are called county commissioners, but boards of more than three members in some cases are elected by districts and called boards of supervisors. In half a dozen states county boards of supervisors are larger bodies (usually from fifteen to fifty members) elected by townships. In several southern states the county boards are also larger bodies, elected by districts, such as the parish police juries in Louisiana and the county courts of justices of the peace in Kentucky, Tennessee and Arkansas. County boards have sometimes been referred to as the legislative branch of county government. While the larger boards are organized on a representative basis, there is little difference in the powers of the two types of boards and very little in the powers of either that can be called legislative. Their main work is administrative, and for such business the larger bodies are unwieldy.

In a few states the power of making appropriations and levying taxes has been placed in a body other than the county administrative board. In some of the New England states these powers are exercised by the state legislature or by the members of the legislature from each county. In Indiana an elective county council has been established in each county for these

purposes, in addition to the board of three county commissioners.

The number, titles and functions of other county officers vary a good deal in the different states. Rhode Island has only two county officers, the sheriff and clerk of court, both appointed by the legislature. The other New England states have about six officers in each county. All the other states have a more numerous list. Usually there is no clearly defined chief executive, but in a few states there have been some steps toward developing one. In some New Jersey counties the chairman of the county board has special powers, as has the president of the Cook county board of commissioners in Illinois. In Alabama and Arkansas the county or probate judge is ex officio chairman of the county board and tends to exercise a large influence in its work. In Georgia in some counties the ordinary is probate judge and chief administrative officer of the county. Within recent years several North Carolina counties have appointed county managers, and Georgia and North Carolina have provided by statute for the adoption of the county manager plan of government. In some of the north central states the county clerk or county auditor is the most important administrative official.

Every county has a sheriff and also a court clerk or county clerk, the latter being usually also secretary to the county board. In some states, e.g. Ohio and Minnesota, the county auditor is clerk of the county board. Most of the states have a local prosecuting officer elected in each county under varying titles, such as prosecuting attorney, district attorney, state's attorney, county attorney and solicitor. In some states these prosecuting officers usually act in judicial districts larger than a county. In most states there is a county judge or probate judge in each county, and sometimes there are both a county judge and probate judge. Most states have county treasurers, county recorders or registers of deeds and coroners. Often there are additional clerks for probate and circuit, district or other courts. In the southern and western states and some others there are county assessors; and in most middle Atlantic and north central states there is a county supervisor of assessments. Outside of New England there are usually elective county surveyors and county or district school commissioners and also county road officers and superintendents of the poor. The latter are usually appointed, as are also county health officers in a number of states.

Terms of county officers vary from two to eight years. In states east of the Mississippi River the terms of different officers often overlap. In the southern states a four-year term is common and in the states west of the Mississippi River a two-year term prevails. In most counties the subordinate staff of county officers is small, but in the populous counties with large cities the number of deputies, clerks and other employees is larger and of more importance. Such positions are in most cases filled and held at the pleasure of their superior officers and are often subject to political and personal influence. In the larger counties of New York and New Jersey and all the counties of Ohio and in a few scattered counties in other states the merit system of civil service has been applied to some extent.

County officers in many states are still paid by fees and commissions for particular services; in other states, where a fixed salary system has been established, fees and commissions, out of which the expenses of the office are paid, are collected by the several officers. This practice often leads to extravagance, waste and inefficiency.

Serious attention has been given to the problems of county government in the United States only in recent years. There were earlier studies in the history of local institutions, but the first attempt at a comprehensive analysis of the existing system was that published by John A. Fairlie in 1906 (*Local Government in Counties, Towns and Villages*). In 1912 a survey of county and town government in Illinois was made for a legislative committee of that state. In 1917 H. S. Gilbertson published *The County: the 'Dark Continent' of American Politics*. Since then there have been detailed studies of county government in a number of states. As a result considerable attention has been drawn to the defects in the present situation and various proposals and efforts have been made to improve conditions.

The principal defects of the prevailing methods may be summarized as follows: the detailed enumeration of uniform requirements in state constitutions and laws without regard to varying conditions; the lack of any definite principle of governmental organization; the long list of elective officials in most states; the failure to concentrate administrative responsibility; and the absence of satisfactory business and financial methods in the conduct of county affairs.

Measures for the improvement of conditions have followed different lines. On the one hand,

there has been a tendency toward increasing state activity through the development of state institutions and activities, such as state hospitals, state roads, state police, state administrative supervision in tax and finance administration and in other fields. Some have indeed suggested that this movement should be carried to the point of abolishing the county.

On the other hand, there have been steps toward a greater variety of local methods by laws classifying counties, by optional laws and in two states (California and Maryland) by constitutional provisions for county home rule. Changes in county government resulting from such measures have been in the direction of a simplification of machinery by abolition of some county offices and by strengthening the position of others, and in some cases of moving toward the development of a chief executive officer. The most recent step in this direction is the North Carolina law of 1927 authorizing county managers in that state.

The complexities and difficulties of county government could also be reduced by the consolidation of small counties into larger units. Several states have laws providing for this; but until recent action in Tennessee there has been little evidence of an inclination to adopt this plan. The consolidation of city and county government in the larger metropolitan areas and proposals for regional government are other measures in the same direction.

COUP D'ÉTAT is a change of government effected by the holders of governmental power in defiance of the state's legal constitution. The practise is presumably of immemorial antiquity, antedating the evolution of the constitutional law which makes government subject to, as well as creator of, legality. But the name has been associated with the actions of Napoleon I in 1799 and Napoleon III in 1851. The fame of these strokes of policy fixed the name in the French language, but the phenomenon is no more characteristic of France than of other nations, except as republican France, making constitutions almost unamendable, compelled changes to take violent forms.

In one fundamental respect the coup d'état is similar to revolution. In either case the organic continuity of law is broken and the validity of law as an abiding object of reverent obedience is seriously impaired. Problems arise, internal and external: how and by whom the new bases of governmental structure are to be laid; whether and how soon and on what conditions the outside world will recognize the new constitutional structure; what degree of continuity there shall be between old and new regimes as to state property, debts, alliances. Such problems beset the empire of Napoleon III in 1852 as they did the Soviet republic in 1918.

As regards process, however, coup d'état and revolution are distinct. Coup d'état is committed when those in governmental office alter in their favor the terms on which their office is held, transforming it from a public trust to a private possession. They suspend or cancel terms and powers of the constitution that they find inconvenient. For example, a president elected for four years declares himself president for ten years or for life, or even emperor; a president or king, hampered by parliamentary opposition, gives his own edicts the force of law; or a general—as in the case of Pilsudski in May, 1926—enters the national capital by force, makes and unmakes presidents and premiers, uses and abuses parliament and effectively rules his country by virtue of the deference universally paid to his will as representative national hero.

A coup d'état is almost invariably sudden in appearance; after long secret preparation it is sprung on the unsuspecting, carried through ruthlessly by preventive arrest of notables, dispersal of representative assemblies, suspension of courts by martial law. Force is its essence but more or less under a veil; violence is not rough but orderly; police or soldiery operate illegally but under military command, so efficient as to make bloodshed and destruction needless or of small amount. In some cases there is a subsequent effort to get the appearance of popular consent by plebiscite—a doubtful compliment, as such elections are controlled, not free, and no feasible alternative is presented to the voter.

A revolution may change government by giving effect to an idea, a public opinion that is widely held but is thwarted by existing law. A coup d'état is more likely to be in the interest of a small group or even an individual. The person may be a dynastic claimant to an existing throne, as in the case of Carol of Rumania, or an ambitious maker of new or revived empire, such

as Napoleon I or III. More significant in the present decade is such a coup d'état as that of Mussolini on January 3, 1925, which is associated with dictatorship. Generally in such a case severe national crisis is produced by impending economic bankruptcy, class war or external danger. The constitutional government is unable to cope with the situation, perhaps because the system separates and sets in opposition political and administrative powers that should be exerted in harmony, perhaps because parliamentary parties divide interests so fundamentally and multifariously that the representative body can agree upon nothing. Government is paralyzed, yet action is imperative. An executive officer or faction leader seizes power outside the law. To enable the state to emerge from the impasse of legal powers abused and used only to deadlock he cuts Gordian knots instead of trying to disentangle them, he brushes aside constitutional law, he suspends individual or group liberties such as the press or the vote and thus enables the state to exert a will. It is his own will, perhaps arbitrary or unintelligent, but even that is regarded as better for the state than deadlock or multi-party parliamentary paralysis, which is no will at all. If public opinion is irresolute, divided, incapable, the hero of such a coup d'état may appeal to public sentiment, which, while less rational than opinion, is stronger and more widely held and is capable of being caught by such spectacles or slogans as a Carol arriving in an airplane or a Mussolini leading impatient youth to revive the grandeur of Rome.

Coups d'état rarely succeed. Manifestly destructive to present legality they incur the opposition of all who have an interest in the status quo. But the vast element of political inertia, at first an obstacle, may by appearance of success be quickly transformed to a support. Masses of men are indifferent, irresponsible, passively accepting whatever seems to have succeeded in asserting itself as authoritative. Coups d'état are gamblers' strokes, favored by those who have little to lose by failure, but a fortune to win in the event of success. Coups d'état have been thwarted, usually in secret by the gamblers' loss of nerve, sometimes in the open by the active resistance of the law abiding. The French king Charles x in 1830, attempting a coup d'état in the interest of autocracy, was checked by the spontaneous popular erection of barricades; and the net outcome of the affair was the bourgeois constitutional regime of Louis Philippe. The Kapp Putsch of March, 1920, was a coup d'état

directed toward restoration of the old regime in Germany. The officers temporarily ousted were able to call out on general strike the working masses who were loyal to the republican regime. The strike paralyzed the coup, and the republican regime was rendered so much the stronger in public opinion and sentiment by the proof it had given of strength to endure severe shock. Generally speaking, coups d'état find success only in case the constitutional regime is suffering extreme and widespread and deep seated unpopularity and unbearable economic or political discontent, with no promising outlook for far reaching legal change of policy or governing personnel.

On the other hand, a coup d'état is a natural, not to say normal, practise in communities that are politically immature, in which immediate objects (economic prosperity of a dominant class or dominance of a favorite political leader) are more highly appreciated than ultimate benefits such as stability and credit—where regard for law as such is undeveloped. Consent of the masses, at least to the extent of not rebelling, may be easy to win by spectacular strokes and temporary appearance of success. It is a slow process to win the public mind by persuasion to the acceptance of a man or an idea. The man who does things may in such a community win wide sentimental adherence, which looks like public order. Most people fail to appreciate the value—to them abstruse and dubious—of right method. They see that order is quickly restored after a coup, and unquestionably machine gun, airplane and censor controlled cheap press and radio do work wonders in this sense. Perhaps it is not duly appreciated that such order is not the rational stable order of willing, sympathetic obedience, but the precarious order of helpless, brutish endurance of the lesser of evils.

It is significant that England's experience with the coup d'état—the armed man Cromwell suppressing Parliament—is nearly three centuries in the past. France suffered more than once from the iron ambition of a Bonaparte and the fascination of that victorious name, but her trouble was yet more the growing pains of her adolescence in constitutional self-government. In the past three generations there has been no serious threat. On the other hand, eastern and southern Europe and Latin America suffer so severe a handicap of past misrule and hence of political backwardness that they still endure earthquake shocks and eruptions of a political energy that is irregular and perhaps, until after long political

experience, incapable of regulation. In their political action one must expect violent shocks until a habit of constitutional law shall have been acquired by usage.

COURCELLE-SENEUIL, JEAN GUSTAVE (1813-92), French economist. After an intensive classical education he studied at the École de Droit in Paris. While director of a metallurgical plant in Lemoisin he was editor of the *National*, Armand Carrel's opposition newspaper, and later the editor of the *Journal des économistes*. Following the outbreak of the Revolution of 1848 he was appointed director general of the public domains in the Ministry of Finance but resigned a few days later when he realized that he could accomplish nothing useful. After the coup d'état of 1852 he left for Chile, where he taught political economy at the law school in Santiago and acted as financial adviser to the Chilean government for several years. Upon his return to France he was appointed councilor of state in 1879 and three years later was elected member of the Académie des Sciences Morales et Politiques.

Courceille-Seneuil was a distinguished member of the liberal school. His contributions include a clear separation of economic theory (plutology) from applied economics (ergonomy) and an analysis of the nature and forms of appropriation. Of the two forms of appropriation, the contractual and the authoritarian, he clearly recognizes the former as the superior and as characteristic of civilization, but he differs from the classical school in that he regards both as

natural outcomes of historical circumstances amenable to the intervention of human will. Courcelle-Seneuil was also a recognized authority on banking and was an ardent advocate of the independence of banks of issue. His *Traité théorique et pratique des opérations de banque* (Paris 1853), now in its thirteenth edition, is still considered a classic in its field.

Courcelle-Seneuil's influence was not confined to the academic field. As counselor of state his advice was sought in matters of economic legislation. His influence was particularly strong in Chile, where he stimulated the study of economics and where his opinions were incorporated in legislation on tariff, banking and allied matters.

COURNOT, ANTOINE-AUGUSTIN (1801-77), French mathematician, philosopher and economist. Cournot was professor of mathematics at Lyons, rector of the Grenoble Academy, inspector general in the department of public instruction and finally rector of the Dijon Academy. Among the university philosophers of his time, most of whom were under the influence of Cousin, he was distinguished by his knowledge of science, particularly of mathematics, to which he made important contributions.

Cournot was preeminently the theorist of chance. In opposition to Laplace, who thought of chance events as occurrences of whose cause we are ignorant, he defined chance as the unpredictable concurrence of two independent causal series and thus attributed to chance as much essential reality as to cause. It was this notion of chance which led him to indicate the importance of probability calculus for statistics, whose aim he described as the coordination of observations for the purpose of establishing numerical relations purged of accidental influences and exhibiting the operation of regular causes.

His belief in the reality of chance underlies also Cournot's distinction between science and

history: the former, he held, deals with laws of nature, constant mathematical relations between two variables, and the latter with material representing a mixture of necessary and fortuitous events. In the field of human history chances are vastly more numerous and rich in consequences than they are in physical nature. Yet the historian may find principles of order present even in the midst of disorder. Cournot's historical etiology refuses to explain everything by "little causes." Although great men play an important part, the success of individuals is conditioned by the concatenation of social forces and man himself is always the product of a social environment. A historian must disentangle the significant from the unimportant, show the predominance of the constitutive element over the immediate cause, discover the main trend of the centuries. Cournot himself sketched something like a philosophy of history. He observed that with the progress of civilization the organic gives way to the mechanical, the calculable is increasingly substituted for the spontaneous, the fixity of mathematical and logical combinations for the disordered movement of life, the rational for the instinctive.

Cournot was also the founder of mathematical economics although he was not the first to employ mathematical methods in this field. He deliberately limited their application to chrematistics, a study of market phenomena based on the assumption that the participatory individuals are governed by an unlimited pursuit of gain. His foremost contribution is the apparatus of demand and supply functions with the aid of which he analyzed not only price formation under conditions of perfect monopoly, duopoly and perfect competition but also the shifting of taxes regarded as an additional cost of production. He did not concern himself with considerations of utility and disutility underlying phenomena on the pecuniary level nor with conditions of a general equilibrium in a market. His treatment of foreign exchanges, of variation in general prices and of social income was less successful.

COURT MARTIAL. Military courts have existed wherever a civilized state has maintained a standing army. Their organization and procedure depend more on the compromise which military authority is forced to make with current ideas of criminal justice than on any historical sequence. It is customary, however, to trace their origin to Roman law. Roman military judges were a permanent part of the judicial system, exercising civil as well as criminal jurisdiction over soldiers. The exact limitations of that jurisdiction are in dispute because of the necessarily increased power of military judges in conquered territory. In feudal times in England a differently organized society created less efficient but more picturesque military justice. Feudal society made no sharp distinction between military and civil duties. One of the king's tribunals after the Norman Conquest was a court of chivalry of *curia militaris*, sometimes called the Constable and Marshal's Court, dealing with matters touching deeds of arms where the common law was inapplicable. Such matters included heraldry and successions to the various feudal dignities not involving property rights. Since the distinction between citizens and soldiers in the feudal state was vague, the jurisdiction of the Constable and Marshal's Court was also vague. Its power increased in time of war, that is, when the courts at Westminster were closed - a definition which has persisted to the present day. In time of peace it was unpopular, as indicated by the Petition of Right of 1628, a protest against its activities. Its traditions and procedure were so alien to a rapidly developing common law and so dependent on an absolute royal prerogative that it disappeared with the feudal system. During the reign of Henry VIII the office of constable was never

filled and the Marshal's Court was finally voted a grievance by the Parliament of 1640. All that survived was a system of military regulations made by the constable and issued by the kings in preparation for war.

With the reign of Charles I courts martial assumed the modern form of boards of specially appointed officers. They were a direct development of the Marshal's Court with its Roman traditions and were guided also by the military usages of the Low Countries, as decreed at Arnheim in 1590, and by the military laws of Gustavus Adolphus. Standing armies became permanent with the Cromwellian revolution. Their discipline seemed to require an exercise of the king's prerogative, subject to strict limitations by a watchful Parliament expressed in articles of war and annual mutiny acts. These mutiny acts were reenacted every year from 1689 to 1879, when they were consolidated with the articles of war in an Army Discipline and Regulation Act, replaced in 1881 by the Army Act. The fact that this act must be passed annually is an interesting survival of the ancient fear of the military power of the crown.

The English court martial system and military code were adopted in America in 1775 by the Second Continental Congress and have not been altered in their essential structure since that time, although the Code of 1916 represented a complete revision in matters of detail. The permanent personnel of the court martial system in the United States consists of the commanding officer with power to appoint the court and execute or disregard its sentences; a staff of technical advisers known as the Judge Advocate General's Department, located at Washington, and staff judge advocates located with the separate commands; and the president, who has the rule making power within the limits of the articles of war and who by executive order issues the *Manual for Courts-Martial*. The courts martial themselves are not permanent bodies and their personnel is determined by the officer appointing them. They are of three kinds, general, special and summary. The first consists of not less than five officers, the second consists of not less than three officers and the third consists of one officer. Their separate jurisdictions depend not on the kind of offense but on the weight of the penalty sought to be imposed. The appointing officer is of higher or lower rank according to the jurisdiction of the court to be convened. Only general courts can try officers or persons charged with capital offenses. They are

not courts in the sense that they may give final judgment. Except in the case of an acquittal their decisions are only advisory.

The machinery of prosecution is an extension of the military command. Public criticism in 1919, led by General S. T. Ansell, acting judge advocate general during the war, resulted in an attempt to make the court martial system less dependent on the commanding officer, and the Army Reorganization Act of 1920 embodied several of these suggested changes. The privilege of preferring charges, hitherto limited to officers, was extended to private soldiers. The commanding officer was compelled by statute to consult his staff judge advocate as to the desirable method of dealing with the charges, a procedure which was previously only a matter of custom. If the case is tried, a specially appointed trial judge advocate, with no training required, occupies the anomalous position of both prosecutor and adviser to the court. All records of the trial are examined by the staff judge advocate who in cases tried by general courts martial submits them also to the judge advocate general. In the office of the latter there is a board of review which must approve sentences involving dishonorable discharge, penitentiary imprisonment or death. Further amendments to the code in 1927 included no important changes.

The jurisdiction of courts martial rests on the Fifth Amendment to the constitution and on the statutory articles of war. Within the limits of these articles the president by executive order issues further regulations called the *Manual for Courts-Martial*. An additional source of legal doctrine and advisory authority is found in the opinions of the judge advocate general, published annually but rarely available in the ordinary court martial trial. The *Manual for Courts-Martial* contains certain gestures of conformity to the language technique of the civil courts, such as the reasonable doubt presumption, the hearsay evidence rule and rules as to the admission of documentary evidence together with a vague direction that the general rules of evidence in criminal trials are to be applied. Since the court gets its legal advice from the prosecuting trial judge advocate there is little evidence of any uniform application of such rules.

The court martial system is designed solely for the discipline of persons declared by statute subject to the military service; hence it deals only with offenses against the articles of war committed by such persons. Extensions of that jurisdiction are supposed to rest only on the

necessities of a state of disorder, when martial law is invoked.

In most states a system of courts martial for the National Guard is recognized. A uniform act has been passed in many states limiting the penalties of the National Guard courts martial to a small fine and providing for the collection of that fine by a system similar to the levy of execution, with the additional penalty of imprisonment for failure to pay.

Naval courts have not the long history of military courts, probably as a result of the almost absolute power of a captain on shipboard and also of the lack of opportunity to extend that power over civilians. Prior to 1645 naval commanders appear to have had absolute power over life and death. In England the first laws for the discipline of the navy were passed by the Long Parliament on the model of the army system. Naval courts martial in the United States today are similar to the army courts in form and procedure.

In England the absence of anything corresponding to the American summary court and the fact that the judge advocate acts only as adviser and not as prosecutor are important differences in the court martial system. The system includes a General Court Martial, a District Court Martial corresponding to our Special Court and a Field General Court Martial appointed in emergencies by officers not ordinarily empowered by warrant of the king to convene a general court martial. Summary punishments up to imprisonment for twenty-eight days are administered by the commanding officer, providing that the offender does not insist on a trial. An interesting variation is the fact that the death penalty for sleeping on a sentry post has been abolished in England since the World War but retained in the United States.

The military courts of France and Germany show greater conformity to ordinary court procedure than the Anglo-American system. In Germany before the war there was a hierarchy of three courts martial with a system of appeals from the lower to the next higher court. Each court included in its membership specially trained law members. After the war each of these courts was stripped of its jurisdiction by the constitution of 1919, and except in time of war and on board warships the military code is enforced by the civil courts.

In France after the revolution an interesting attempt was made to handle military justice by civil procedure. A system of grand and petty

COURT MARTIAL. Military courts have existed wherever a civilized state has maintained a standing army. Their organization and procedure depend more on the compromise which military authority is forced to make with current ideas of criminal justice than on any historical sequence. It is customary, however, to trace their origin to Roman law. Roman military judges were a permanent part of the judicial system, exercising civil as well as criminal jurisdiction over soldiers. The exact limitations of that jurisdiction are in dispute because of the necessarily increased power of military judges in conquered territory. In feudal times in England a differently organized society created less efficient but more picturesque military justice. Feudal society made no sharp distinction between military and civil duties. One of the king's tribunals after the Norman Conquest was a court of chivalry of *curia militaris*, sometimes called the Constable and Marshal's Court, dealing with matters touching deeds of arms where the common law was inapplicable. Such matters included heraldry and successions to the various feudal dignities not involving property rights. Since the distinction between citizens and soldiers in the feudal state was vague, the jurisdiction of the Constable and Marshal's Court was also vague. Its power increased in time of war, that is, when the courts at Westminster were closed—a definition which has persisted to the present day. In time of peace it was unpopular, as indicated by the Petition of Right of 1628, a protest against its activities. Its traditions and procedure were so alien to a rapidly developing common law and so dependent on an absolute royal prerogative that it disappeared with the feudal system. During the reign of Henry VIII the office of constable was never

filled and the Marshal's Court was finally voted a grievance by the Parliament of 1640. All that survived was a system of military regulations made by the constable and issued by the kings in preparation for war.

With the reign of Charles I courts martial assumed the modern form of boards of specially appointed officers. They were a direct development of the Marshal's Court with its Roman traditions and were guided also by the military usages of the Low Countries, as decreed at Arnheim in 1590, and by the military laws of Gustavus Adolphus. Standing armies became permanent with the Cromwellian revolution. Their discipline seemed to require an exercise of the king's prerogative, subject to strict limitations by a watchful Parliament expressed in articles of war and annual mutiny acts. These mutiny acts were reenacted every year from 1689 to 1879, when they were consolidated with the articles of war in an Army Discipline and Regulation Act, replaced in 1881 by the Army Act. The fact that this act must be passed annually is an interesting survival of the ancient fear of the military power of the crown.

The English court martial system and military code were adopted in America in 1775 by the Second Continental Congress and have not been altered in their essential structure since that time, although the Code of 1916 represented a complete revision in matters of detail. The permanent personnel of the court martial system in the United States consists of the commanding officer with power to appoint the court and execute or disregard its sentences; a staff of technical advisers known as the Judge Advocate General's Department, located at Washington, and staff judge advocates located with the separate commands; and the president, who has the rule making power within the limits of the articles of war and who by executive order issues the *Manual for Courts-Martial*. The courts martial themselves are not permanent bodies and their personnel is determined by the officer appointing them. They are of three kinds, general, special and summary. The first consists of not less than five officers, the second consists of not less than three officers and the third consists of one officer. Their separate jurisdictions depend not on the kind of offense but on the weight of the penalty sought to be imposed. The appointing officer is of higher or lower rank according to the jurisdiction of the court to be convened. Only general courts can try officers or persons charged with capital offenses. They are

not courts in the sense that they may give final judgment. Except in the case of an acquittal their decisions are only advisory.

The machinery of prosecution is an extension of the military command. Public criticism in 1919, led by General S. T. Ansell, acting judge advocate general during the war, resulted in an attempt to make the court martial system less dependent on the commanding officer, and the Army Reorganization Act of 1920 embodied several of these suggested changes. The privilege of preferring charges, hitherto limited to officers, was extended to private soldiers. The commanding officer was compelled by statute to consult his staff judge advocate as to the desirable method of dealing with the charges, a procedure which was previously only a matter of custom. If the case is tried, a specially appointed trial judge advocate, with no training required, occupies the anomalous position of both prosecutor and adviser to the court. All records of the trial are examined by the staff judge advocate who in cases tried by general courts martial submits them also to the judge advocate general. In the office of the latter there is a board of review which must approve sentences involving dishonorable discharge, penitentiary imprisonment or death. Further amendments to the code in 1927 included no important changes.

The jurisdiction of courts martial rests on the Fifth Amendment to the constitution and on the statutory articles of war. Within the limits of these articles the president by executive order issues further regulations called the *Manual for Courts-Martial*. An additional source of legal doctrine and advisory authority is found in the opinions of the judge advocate general, published annually but rarely available in the ordinary court martial trial. The *Manual for Courts-Martial* contains certain gestures of conformity to the language technique of the civil courts, such as the reasonable doubt presumption, the hearsay evidence rule and rules as to the admission of documentary evidence together with a vague direction that the general rules of evidence in criminal trials are to be applied. Since the court gets its legal advice from the prosecuting trial judge advocate there is little evidence of any uniform application of such rules.

The court martial system is designed solely for the discipline of persons declared by statute subject to the military service; hence it deals only with offenses against the articles of war committed by such persons. Extensions of that jurisdiction are supposed to rest only on the

necessities of a state of disorder, when martial law is invoked.

In most states a system of courts martial for the National Guard is recognized. A uniform act has been passed in many states limiting the penalties of the National Guard courts martial to a small fine and providing for the collection of that fine by a system similar to the levy of execution, with the additional penalty of imprisonment for failure to pay.

Naval courts have not the long history of military courts, probably as a result of the almost absolute power of a captain on shipboard and also of the lack of opportunity to extend that power over civilians. Prior to 1645 naval commanders appear to have had absolute power over life and death. In England the first laws for the discipline of the navy were passed by the Long Parliament on the model of the army system. Naval courts martial in the United States today are similar to the army courts in form and procedure.

In England the absence of anything corresponding to the American summary court and the fact that the judge advocate acts only as adviser and not as prosecutor are important differences in the court martial system. The system includes a General Court Martial, a District Court Martial corresponding to our Special Court and a Field General Court Martial appointed in emergencies by officers not ordinarily empowered by warrant of the king to convene a general court martial. Summary punishments up to imprisonment for twenty-eight days are administered by the commanding officer, providing that the offender does not insist on a trial. An interesting variation is the fact that the death penalty for sleeping on a sentry post has been abolished in England since the World War but retained in the United States.

The military courts of France and Germany show greater conformity to ordinary court procedure than the Anglo-American system. In Germany before the war there was a hierarchy of three courts martial with a system of appeals from the lower to the next higher court. Each court included in its membership specially trained law members. After the war each of these courts was stripped of its jurisdiction by the constitution of 1919, and except in time of war and on board warships the military code is enforced by the civil courts.

In France after the revolution an interesting attempt was made to handle military justice by civil procedure. A system of grand and petty

juries was used by military courts and their jurisdiction extended over civilians, provided the offense charged violated the military code. The attempt was a failure. Juries were suppressed by Napoleon in 1806. The permanent courts remain, however, with permanent official staffs in each military department, subject to military courts of appeal. There is a final appeal in limited instances to the Court of Cassation. The procedure imitates the civilian procedure in France in that it is more like a judicial investigation than an Anglo-American trial. The president may suspend the right of appeal during a time of emergency, and this was done during the early part of the World War. During the first years of the war summary trials by special courts were resorted to which were later abandoned, as a result of public disfavor. Officers of military police, or *prévôts*, have a summary jurisdiction without any form of procedure and may impose as much as six months' imprisonment. The military courts of appeal, however, go to the other extreme in formality and include in their membership two civil appellate judges, one of whom presides. They can reverse only for errors of law.

An organized court martial is the gesture which military power makes to current ideas of criminal justice. Discipline, the paramount purpose of the army code, is based on obedience to the individual. The conception of a rule of law and not of men, difficult to reconcile with army organization, finds its only expression in military courts. But in the army its place must be subordinate and formal. Therefore the contribution of courts martial to legal logic or philosophy has been negligible. For this reason a lack of uniformity of results in similar cases has always been noteworthy. This may in part be explained by the fact that a systematic conceptual way of explaining results makes civil courts seem more uniform than they really are, and in part by the fact that individualization of punishment is the most effective device of the disciplinarian.

In its efficiency in obtaining convictions the system is unique. Out of over 68,000 cases tried in general and special courts martial during the two years ending June 30, 1919, there were convictions in more than 85 percent. This has led a few eminent jurists to say that there is some magic in the system which civil courts would do well to learn. Yet this magic probably consists only in the fact that where procedure and legal concepts become mere ritual a court is more free to do as it pleases and that the aims of military

discipline are relatively so simple that military courts are surer of what they please to do. The most important thing which civil courts can learn from courts martial is that where judges are so sure of desired results that they dare to arrive at them in a direct way without the aid of mystical abstractions they invariably cause intense popular resentment.

COURT, PIETER DE LA (1618-85), Dutch writer on politics and political economy. He was a wealthy textile manufacturer and merchant in Leyden at a time when the industry was flourishing and exporting to all countries. Entrepreneurs were rebelling against the control of the guilds, the public markets and the monopolies of the Indian trading companies. De la Court was the

spokesman of his industry in these causes. Viewing intemperance as detrimental to economic welfare he argued also for religious liberty and defended the academic freedom of the University of Leyden.

His chief economic work, *Het welvaren van Leiden*, defending the new liberal views, was written in 1659, but since it was not printed in a complete edition until 1911 (The Hague, with German translation by F. Driessen) his influence on the development of political economy was slight. He published under the name of van den Hove (Dutch for de la Court) his *Interest van Holland ofte gronden van Hollands welvaren* (Amsterdam 1662), which was republished as *Aanwijzing der heilsame politieke gronden en maximen van de republiek van Holland en West-Friesland* (Leyden 1669; 2nd ed. Rotterdam 1676) and translated into English (London 1702). This essentially political work was a defense of the anti-Orange party, the *staatsgezinde* whose leader, Jan de Witt, had been his collaborator on the book. When the party fell in 1672 de la Court fled the country.

COURT, ROYAL. *See* ROYAL COURT.

COURTNEY, FIRST BARON, LEONARD HENRY COURTNEY (1832-1918), English economist and statesman. Courtney was a fellow of St. John's College, Cambridge, and was called to the bar, but he found his occupation in the office of the *Times*, where he became a leader writer in 1864. In 1880 he became undersecretary of the Home Office and in 1882 financial secretary of the Treasury, the highest office below the cabinet. In 1884 his official career, which had begun with such promise, was cut short by his own action. He resigned because Gladstone would not include proportional representation in his new franchise bill. Two years later the Liberal party split over home rule and Courtney took the Unionist side; but he was not happy in his new party, for although a Unionist he was a determined opponent of imperialism, and imperialism was now in the saddle. He was the most effective critic of the government's

handling of the Jameson raid in 1895 and when the South African War broke out in 1899 he was the leader of the Peace party. In 1906 he stood for West Edinburgh as a Liberal; after his defeat he was made a peer by Campbell Bannerman. He gave a general support to the Liberal government, but he was an active critic of its foreign policy. In the Great War he pleaded for moderation and for trying every avenue to peace.

Courtney held a unique position in British politics. He shared Mill's intellectual inheritance with Fawcett and Westlake. The causes nearest to his heart were not party causes; they were proportional representation and women's suffrage. He was a Unionist, but not for the usual reasons; he held in 1886 that another effort should be made to reconcile England and Ireland within the Union. He was universally respected for his integrity and his independence.

JOHN LAWRENCE HAMMOND

Consult: Gooch, G. P., *Life of Lord Courtney* (London 1920).

COURTS. A court is popularly conceived as that part of the communal organization whose function is to determine disputes between individuals or groups, whether or not the disputants are in some way representative of the community. Despite its abstract name a court as it exists concretely is always a man or a group of men. One man may sit as a court or it may be composed of the entire number of adult citizens. In either case the court is to be regarded as an institution. Members of a court may perform many other functions, but they are a court only if and when they try an issue.

Accordingly, it is extremely unlikely that there are or were communities without courts of some sort, since it is almost impossible that there are or were communities in which there never was an occasion for dispute. But courts do not emerge as institutions until they are to some degree formalized; that is to say, until the method, the time, the person or the place required for a trial of issues is established by custom or statute and until only issues so determined engage the authority of the entire community. In such a developed form courts have appeared in many parts of Europe and Asia and especially in Africa, but they have not been found to any noticeable extent among the Indians of North and South America.

It may properly be said that until such a development has taken place, systems of law proper do not really come into being; in other

words, there is no possible differentiation between the law and the other mores of the community by which are formulated its religious and moral activities and its daily habits of dress and intercourse. Law is distinguished by being that body of practises upon which courts have pronounced judgment or will or may pronounce judgment, and practically there is no other test. This explains the overwhelming importance of courts in legal history. Indeed, early legal history is almost exclusively concerned with describing the organization of courts and the procedure which prevails in them. Such law as exists has been correctly described as secreted in the interstices of procedure.

The judicial function was nearly always a highly prized privilege and nearly always a prerogative of the ruling class. Generally those who conducted the administration kept within their hands the management of the courts as well, but the fullest development of courts was reached only when they were completely detached from other instruments of government and when the office of judge became a profession which was the exclusive business of selected persons. This development was attained in the later Roman Empire and in Europe, especially in England, after the twelfth century.

But the degree of independent development of courts is not necessarily correlated with the complexity of the political organization. A highly intricate administrative system might exist, as in Ptolemaic and Roman Egypt, in which court and executive were scarcely severed at all. And among the west African tribes an elaborate development of courts is found side by side with a relatively insignificant political growth. In the main, however, a loose organization in which political functions are themselves of secondary importance and partly undifferentiated implies a similar vagueness in the operation and differentiation of courts; and a specialization in the one field is accompanied by a similar development in the other.

Were early courts essentially bodies of private arbitrators? Such a statement is often made because it fits into a schematic presentation of the growth of courts, but it is actually very doubtful in any exact sense. Where our documents are fullest it seems clear that private arbitration, which in practise must have been often resorted to, was at first ignored or barely tolerated by the courts but finally and to varying degrees sanctioned by them. The result was sometimes that the custom of friendly arbitra-

tion created institutions which were like courts and were ultimately absorbed into the judicial system; and sometimes, as at present in the United States and England, the result was that arbitral agencies secured a partial authority from the courts themselves in the enforcement of their judgments. It may be said for the most part that court activity, instead of being private in its origin, arose through the gradual dissociation of the judicial from the executive functions of the magistrate, who was anything but an arbitrator. Only during the so-called classical period of the Roman law and in post-Tudor England, however, did the dissociation become sharp enough to make a judge differ externally from a private arbitrator except in the authority of his utterances.

It is not easy to generalize about "primitive" law because primitive tribes were and are extremely varied. If we consider chiefly conjectures about the primitive antecedents of present legal systems, it is possible, however, to mention various leading characteristics. In primitive courts the distinction so familiar to us between civil and criminal courts does not exist. It is the redress of personal grievances that is sought in all cases. Criminal courts arise when the accuser has no personal grievance whatever and appears in a representative capacity only. Again, primitive courts are not so much directly engaged in judging disputes as in guaranteeing the accuracy of the complicated ritual of early procedure. It is probably this fact which has given rise to the idea that the judges must at first have been arbitrators. But it appears that the enforcement of the result which a correctly performed ritual sought was practically compulsory; and oaths, ordeals, spells and formulae make their appearance almost everywhere. Even in what we may call the most primitive stages the enforcement of justice was never absent from the avowed purpose and practical outcome of court activity. Moreover, since the ritual was all important, the initiator of proceedings always had an enormous advantage. In fact, the court was a mere instrumentality by which the initiator could get what he claimed and most decisions were necessarily for the plaintiff. But in small communities it could scarcely have happened often that a claimant would put the ritual procedure in motion to secure a result which the community would condemn, and this is only another way of saying that he would scarcely have the effrontery to make an obviously unjust claim. Another

characteristic of primitive courts, which also tended to prevent this, was the fact that they were public and held in the open. They were public because the time and place of their sessions were known or soon came to be known and because the people who assembled to listen and observe were an essential part of the court. The requirement that the court be held in the open may have had some connection originally with religious notions, but these again might have been nothing more than a rationalization of practical need, since few ancient buildings could accommodate a crowd.

When the early codifications begin, it becomes easier to observe the organization of the courts. But while in almost all cases the purpose of codification was at least partly reformatory, it rarely succeeded in changing the court system, which was too closely connected with religion and the need for supernatural security to be lightly tampered with. The result of codification was thus usually to fix the organization and operation of the courts to such an extent that even slight modifications of their jurisdiction and activity became difficult to justify. In all likelihood it is this fact that created the need, which courts felt, of achieving the ends of justice by various evasive devices, which, however, soon hardened into technicalities and under changed circumstances defeated the very purposes for which they were created.

The famous code of Hammurabi indicates a considerable development of legal institutions. Yet a complete detachment of the courts from the administrative organization does not appear. Moreover, the dissociation of the court from the religious organs was never quite complete. This is shown by the fact that the place of the court was regularly a temple even in those later days when the priests instead of being the judges themselves were merely expert advisers in regard to the procedural ritual. Although the judge was an administrative official he sometimes bore a judicial title, and although also a royal official he was a local officer continuing the powers of an older functionary of the autonomous city-state. But under the great Hammurabi the royal power reached nearly its maximum of centralization. The king appeared as the professed father, patron and judge of his people with the specific purpose of establishing peace in their personal relations and of protecting the weak against the strong. It is this paternalistic attitude which explains the requirement that the judge should attempt a

reconciliation between the parties before proceeding to an issue. The judge's retention of executive and administrative functions helped to effect such compromises, as well as the execution of the judgment if the case was tried.

That there ever was a popular element in the court is unlikely. A council of elders who appeared as witnesses, as investigators, as legal experts and advisers, sat with the judge in important matters. They exercised no control over the proceedings except by the weight of their personal authority, and it was not their verdict but the magistrate's judgment that was decisive. There is a distinct indication, however, that these elders were an extremely ancient institution, so ancient indeed that the term for court was sometimes derived from them. It is possible therefore that the magisterial and official character of the judge is a later development.

In the Assyrian monarchy a royal emissary came to discharge judicial, fiscal and administrative functions, displacing local and communal tribunals. But in the intricate bureaucracy of Egypt there is not to be discovered even a tendency toward the differentiation of judicial from administrative functions or any hint of a popular jurisdiction. The administration of justice was given a set cast which it always retained. Transmitted to the Ptolemaic kingdom it affected profoundly the later Roman system. Especially to be noted is the system of record in the Egyptian courts. There was a great deal of signing, transcribing, recording and authenticating. Secondly, the right of appeal, usually invoked in writing, was permanent. The poorest peasant might ask justice of the king after he had exhausted the ordinary forms of recourse. But the extreme interpenetration of government and courts made justice dependent more than elsewhere on the strength and vigor of the central authority. Not merely a powerful king but a vigorous and active system of inspection was necessary to insure the proper working of a system of this sort. In Egypt consequently the outcry against the cruelty and oppression of the governor is a constant burden, and periodic visitation such as the reforming Pharaoh Hammurabi instituted did not effect much that was permanent.

In ancient Greece a notable development of democratically organized courts took place. By Greek tradition the oldest Athenian court, the Areopagus, was also the oldest senate, or *boule*. If the Homeric king is recalled, who did justice, as all ancient kings did, aided by god give

themistes, specific divine directions for each event, it becomes apparent that this ancient court and council was simply, as its name implied, the adviser, sponsor and later the master of the judge proper, the magistrate himself. When the oligarchy succeeded the monarchy in the seventh century and the king's functions were divided among the nine archons, the magistrate's function became an honorary presidency and the council became the body of judges. The democratization of Athens simply transferred the court function as it did the legislative function to the assembly of free citizens. One of the reforms of Solon was to allow a right of appeal from the decisions of the magistrates to the people assembled in the Heliaca, the judicial assembly, as distinguished from the Ecclesia, the political assembly. In the time of Cleisthenes these so-called heliastic courts became courts of first resort. The magistrates now merely prepared cases for trial and presided over the heliastic court when they were heard. The whole body of 6000 heliasts became too large and was compelled to segregate itself into sections, or divisions, called dicasteries. This was done by lot and each section was officially the whole body of Athenians. The members were addressed by the formal political title of "citizens of Athens," never "judges" or "gentlemen of the jury"; and the large size of these bodies, several thousand in some cases, made them seem virtually a body of citizens assembled in their political capacity.

An important reform was introduced in the tyranny of Pisistratus, which was reestablished by the restored democracy in 453-52 B.C. To help remove the congestion of the ordinary courts resulting from the existence of restrictions upon the jurisdiction of the subject cities thirty itinerant judges were created to hear cases in the Attic countryside. When the thirty tyrants were overthrown, the itinerant justices were replaced by the Board of Forty sitting at Athens only. A form of public arbitration was also introduced about this time. Through this period the Areopagus continued to exercise jurisdiction in cases of wilful homicide. Other courts to try lesser degrees of homicide also existed, the so-called ephetic courts, recruited from the membership of the Areopagus.

It has been inferred that the law administered by the Athenian popular courts was a refined sort of mob law, fluctuating and arbitrary and determined by easily roused passions. But it is to be remembered that much of our information

is obtained from the Athenian orators, and a system of law or courts can scarcely be evaluated solely upon the basis of the harangues of special pleaders. The extant judicial orations of Demosthenes, Lysias and other Athenian orators appeal as much to passion and prejudice as do modern jury speeches. It is none the less a fact that a system of popularly organized courts like that of Athens made it extremely difficult for a class of professional jurists to arise, and such a class is essential for a highly organized judicial system administering a scientific body of law.

The history of Rome exhibits the evolution of courts from primitive forms in the regal period to a highly organized structure of a subordinated hierarchy of jurisdictions in the late empire. The consuls succeeded to all the powers of the kings, but by the *Lex licinia* in 367 B.C. civil jurisdiction was vested in the *praetor urbanus*, and in 242 B.C. the *praetor peregrinus* was created for suits involving aliens. In 494 B.C. the aediles were established; they were administrative policing officers but had jurisdiction over cases involving nuisances and certain kinds of market sales. The number of the praetors and aediles was increased as Rome expanded.

Throughout most of Roman legal history the single judge type of court may be said to have predominated in civil cases. But in the classical period of the Roman law a twofold process came to prevail whereby different agencies really had charge of a case in its preliminary and final stages. The praetor merely organized the case and sent it for decision to a *iudex* selected by the cooperation of the parties. Modern investigations incline to the view that the *iudex* succeeded the private arbitrator, but there are still weighty and unrefuted objections against this conclusion. In complex cases more than one *iudex* might be appointed. In cases involving the claims of foreigners, the judges—the so-called *recuperatores* whose character remains obscure—were also plural. According to some Romanists the formulary procedure was first applied by the *praetor peregrinus* but others believe it to be due to the *Lex aebutia*. There existed also permanent tribunals, the ancient *centumviral* and *decemviral* courts, about which very exact knowledge is also not available. The former were distinguished by the fact that the archaic procedure of the *legis actiones* persisted in them after its abolition in the other Roman courts; according to Cicero

it had jurisdiction in such matters as succession, guardianship and quiritarian ownership; the decemviral court appears to have had jurisdiction in some matters of status.

In criminal cases the jurisdiction of the consuls was limited by the *Lex valeria* in 509 B.C., which gave Roman citizens a right of appeal to the *comitia centuriata*, the popular assembly, when the sentence was death or scourging. Permanent criminal courts developed in the last two centuries before the Christian era as even better guaranties of popular rights—the so-called *questiones perpetuae*. These tribunals each tried separate types of crimes. The presiding judge was either one of the praetors or a special *iudex questionis*. The decision was left to the *consilium*, a jury of Roman citizens.

Under the empire the old Roman judicial system was gradually superseded. The division of the judicial process between magistrate and *iudex* was abolished, and the former now kept jurisdiction of a case until final judgment. A bureaucratic judicial system of higher and lower courts came into existence. The most important judicial officer became the praetorian prefect, and the auditory of the praetorian prefect was a great central court to which appeals ran from all parts of the empire. Under the republic appeals in civil cases had been practically impossible. Some of the greatest Roman jurists were praetorian prefects: Papinian, Paul, Ulpian. The Roman judicial system had produced what had been lacking in all the older systems of the Mediterranean basin, a body of professional jurists. Even under the republic the *iudex* who was a private citizen had found himself more and more compelled to rely upon the advice of the jurisconsults, and especially from the time of Augustus he was compelled to do so. Under the empire the personnel of the courts came naturally to be selected from the professional jurists.

The rise of Christianity brought into existence a system of tribunals that were destined to play a far reaching role in the development of European law. Pious Christians, just as pious Jews, were forbidden by their spiritual chiefs to have recourse to the pagan courts and were required to submit their difficulties to private arbitration or to the decision of their bishops. This form of voluntary jurisdiction, the *audientia episcopalis*, had assumed considerable proportions when the imperial Roman system became manned by Christians and the reason

for abstention disappeared. The episcopal tribunals, however, far from disappearing, gathered new strength by the gradual decay or forcible destruction of the imperial administration in the West, and about 600 the writings of Pope Gregory indicate an enormously extensive jurisdiction responsible to the Roman See and covering almost the entire range of possible legal relations, secular as well as spiritual. Nor did church courts disappear with the growth of the feudal system but remained the peculiar court of the clergy, and from the eleventh to the fourteenth centuries they again began to encroach upon the jurisdictions of the temporal courts.

Tribal courts at first administered justice among the Germanic peoples which established themselves as territorial states in western Europe. The Frankish customs, which had so wide and profound an influence, are best known, and enough is known of the others to make it unlikely that the Franks had much that was unique or peculiar to themselves. The characteristic element in these tribal systems was the judicial authority of the popular assembly, the Thing. It may have been quite a general institution among all the peoples of Indo-European speech; in these ruder societies of the German forest the control by the armed warriors of everything which might lead to feuds between sects or families was permanent and active.

The tribally selected judge was the *thuingin*. When the tribal organization was transformed into a territorial state and the tribal king invested with some of the trappings of the Roman *imperium*, the *thuingin* was displaced by the count (*Graf*), a royal official. But both the *Graf* and his predecessor were judges only in the sense that they guaranteed the regularity of the procedure and assured the execution of the judgment. The judgment itself was the work of the assembly confirming the special verdict of a group of semireligious advisers or counselors, the *rachimburgi*. Among the Franks they were seven in number and formed a committee of the hundred, and after Charlemagne they became a permanent council. In this respect the German court consciously differed, as an ancient gloss reveals, from the only court with which it could be compared, the church court, in which, following the late Roman system, the official judge conducted the trial, declared the judgment and issued execution.

Ritual ideas clung to the court and showed themselves in the fixed time of its meeting,

which was usually every six weeks, and of its duration, which was regularly three days. There was perhaps also present in the number of the tribal division which constituted the court assembly proper the hundred, which soon ceased to have any special significance. But what marked the German court particularly was that attendance upon it was obligatory for all the freemen of the hundred. The obligation was felt to be a great burden, and one of the most popular reforms of Charlemagne was the edict which reduced the days of assemblage to nine throughout the year.

The growing complexity of life and economic organization increased the number and kinds of courts and affected their organization. There were lower or special courts for small matters summoned at intervals where and when the *Graf* or his vicar chose. In the special courts permanent lay judges (*Schoffen*) developed and it was they who found the judgments, and even in the regular courts they later obtained this power. The appearance of a royal court, which followed the king and in which he himself did justice directly, indicates that the king's court, modeled on the Roman system, stepped almost as a matter of course into all the gaps which the customary organization showed. When to this is added the system of *missi*, royal commissioners sent out by Charlemagne to examine, adjudge and report, the idea of assize and circuit courts appears as well as the notion of a residual justice in the central authority from which in due time was to come the corrective element of legal administration.

This corrective element was applied as part of the movement which created the modern national state and broke up the feudal system. Under it a host of private jurisdictions developed, administering justice over small territorial units. The feudal lord maintained the ancient custom of the hundred court, upon which attendance was compulsory, over which he or his steward presided and in which all adjustments of difficulties between vassal and vassal, and vassal and lord were made. With the tightening of the feudal structure the primary purpose of the local court was to maintain and to aggrandize the lord's power. No small element of that power was the unrestricted penal jurisdiction of which the avowed principle was the maintaining of order by frequent, drastic and savage punishments. Civil disputes concerned the only property of real importance—the land. The local court under the imme-

diante control of the lord must have soon ceased to be anything else in such questions than an instrumentality for sharpening and confirming his expanding claims. Indeed, the court system and its administration was one of the most prized and bitterly defended rights of feudal tenure.

The national king could emerge only from a successful struggle with the lords, great and small, whose almost incredibly complex interrelations had formed something very like a caste. There can be little doubt that the Carolingian scheme was the conscious model toward which the new monarchies directed their efforts; and the system of an ambulatory court, sent out by the king or following him and demanding an account of justice done in the local courts or supplementing that justice, was a ready means for the purposes entertained. The king's court appeared a refuge to the oppressed vassal.

Nowhere can the progress of this struggle between the king's justice and local justice be better followed than in England. The Anglo-Saxon tribunals administered local tribal systems under local superintendence. There was no king's court in any proper sense except as a court coordinate with those of other lords, just as there was no general legal custom of the whole country. But when the conquest introduced into England Norman feudalism, which was itself patterned on the Carolingian monarchy, it gave a large scope to the central authority, in that the king made a direct claim on the allegiance of the vassals of his earls and barons. The continental preoccupations of the early Norman kings put England under the immediate control of a minister who characteristically bore the title of justiciar. It was in fact by the intrusion of the king's justice into the local communal jurisdictions of hundred, shire and moot and the seigniorial jurisdictions of courts baron and courts leet that his authority was most strikingly brought home to Englishmen and constituted the strongest weapon forged against the growing strength of the great lords. Of the political side of the struggle it may be said that the power of the nobility was at its height in the thirteenth and fourteenth centuries and created a permanent result of their triumph in the peculiar English development of the Norman parliament. But the gathering control by the royal or central power over the courts and the displacement of local jurisdictions by the king's courts was more than adequate compensation. It was Henry II and

Edward I who accomplished the great constructive work of centralizing English justice, and never after the end of the thirteenth century was it beyond royal control. The office of justiciar ceased to exist after 1234.

From the *Curia Regis* evolved the general courts of the realm by the process of separating the judicial functions of the king's councilors from their executive and administrative ones. The three great courts of the common law, as they are called, came to be the Court of Exchequer, the Court of Common Pleas and the Court of King's Bench. The courts were at first ambulatory, following the person of the king, but gradually ceased to be so. It is not easy to explain briefly the ill defined jurisdictions of the three courts, which in most cases were concurrent and led to a great deal of rivalry. It is likely that the tendency of the courts to think of themselves as marked out by special privileges to be closely and jealously guarded was characteristic of mediæval psychology. At all events, Westminster offered a double escape from the limitations and archaic procedure of the local courts and the overwhelming weight of the lord's influence there.

The king's exchequer found itself exercising the functions of a court in determining the validity of fiscal exemptions and in enforcing the debts due to the crown. But it soon began its career as a court of common law by asserting successfully a general jurisdiction by means of more or less ingenious fictions: for instance, the allegation that the plaintiff was indebted to the crown but that because of the defendant's refusal to pay his debt he could not meet the royal obligation. In revenue cases the barons of the exchequer heard pleas of the crown. In opposition to these were common pleas, or pleas between subject and subject, which came to be entrusted to the Court of Common Pleas. It had its origin in 1178 when Henry II appointed justices to sit at Westminster to render right to all comers. In 1272 a separate chief justice was appointed for the Common Pleas. An exclusive jurisdiction secured by the Common Pleas was over real actions, and thus in cases of trespass it adjudged pleas of the crown. The Court of Common Pleas was the first to become a fixed court. It was so provided in Magna Carta. The Court of King's Bench was at first less an organized body than the method by which the king in person heard those disputes which by their intrinsic importance and the position of the litigants could be heard no-

where else. Although the King's Bench had a chief justice as early as 1268, a number of historical accidents, among them the absence of Richard from the kingdom and the minority of Henry III, retarded its development as an independent bench. From its particularly close connection with the king it derived, however, great prestige. It secured original and appellate jurisdiction in both civil and criminal cases. It was the court that could issue the prerogative writs such as *certiorari*, *habeas corpus*, prohibition, *mandamus* and *quo warranto*. Error lay from the Common Pleas to the King's Bench. The extensive original civil jurisdiction which the King's Bench secured was largely at the expense of the Common Pleas, which was hampered by an inferior procedure. This original jurisdiction was based upon pleas of the crown, and it made particularly great use of the writ of trespass, which came to cover an exceedingly wide field.

The growth of the royal courts represented a process of centralization. A degree of decentralization was necessary if seeking the king's justice either at Westminster or elsewhere was not to become an intolerable burden. The mechanism adopted was the familiar one of visitation by itinerant justices in periodic rounds of the country. This began soon after the Norman conquest, but the commissions issued were intended primarily for inquisitorial purposes, to secure information of wrongs the prosecution of which might fill the royal treasury. Not only the king's power but also his exchequer was enriched by the felon whose goods were forfeited as his blood was corrupted. These early justices on General Eyre, as it was called, spread such terror that commissions of these kinds became obsolete. The chief commissions which survived for the trial of crimes were those of Oyer and Terminer and Gaol Delivery. The justices delivered the jails and inquired into the methods of local tribunals. The king's justices had the great advantage of being able to offer trial by jury, which alone prevailed in the administration of royal justice. But if trial by jury was better than ordeal or combat, it must not be supposed that the king's court either at Westminster or in its peregrinations from assize to assize was a place where an accused could expect indulgence. This was prevented by the pecuniary interest of the king in criminal justice. Its absence in cases of minor offenses, where no forfeiture took place, had a great deal to do with the early establishment of

one of the most characteristic of English institutions, the office of the justice of the peace, which was brought into existence by statute in 1327. It ultimately put the control of the daily lives and happiness of the great mass of Englishmen into the hands of the landed gentry.

In civil cases the jurisdiction at first conferred by the commissions of assize was limited to certain possessory actions. But by the Statute of Westminster II in 1285 the justices of assize were given a general civil jurisdiction over cases begun in the Common Pleas or King's Bench. This statute established the so-called *nisi prius* system, for it provided that cases should not be tried in the two latter benches *nisi prius* (unless before then) the justices of assize failed to come into the country to do so. The circuit system thus established was later extended to other courts and to criminal as well as civil cases, and the holding of the assizes ceased to be occasional and became fixed and periodic. The harmonious growth of the law was insured despite this decentralization by the fact that the judges of the three benches also went on circuit and by the adjournment of difficult cases into the courts of Westminster. The circuit system thus evolved in its main features still endures today.

During these centuries there began to take shape a peculiar limited appellate jurisdiction in Parliament, later confined to the House of Lords and still exercised by it. Probably it arose from the sitting of the king and his council in Parliament and from the growing idea of Parliament as the maker of new law. But from the residuary justice which still remained in the king and his council there developed, particularly in the course of the fifteenth century, a far more important peculiarity of the English judicial system, which indeed became established as its most marked feature. The emergence of a separate court of equity meant that English justice was to be administered by a dual system of courts of common law and equity which, although at first in actual and later in theoretical conflict, nevertheless were to bring about a harmonious development of English law.

It was not long after the common law courts had gained the ascendancy over the local courts that they began to develop difficulties and vices of their own. Their procedure became stereotyped and limited in range. Their fees were high, and corruption and oppression became relatively frequent. It was the jurisdiction of the common law courts which now needed

supplementing and correcting, and it was the king's greatest officer and closest personal adviser, the chancellor, who in the king's name offered the courts newer writs on occasion and undertook to do justice where the king's court had failed or was helpless. It was not long before this occasional and exceptional interference made the Chancery a court proceeding according to settled equitable principles. It perhaps first began to assume something of the regularity and permanence of a real tribunal when the practise of creating charitable uses grew up—an indirect form of transferring property, in which the church was vitally interested and upon which the crown looked without disfavor because it powerfully limited many troublesome feudal claims and privileges.

The Chancery, which had a specific and peculiar business besides the vague jurisdiction which it derived from the residual royal power, grew slowly into a court with its own special forms and procedure, its own body of apprentices and even its own vices. Its characteristics were that there was no jury, that written forms were predominant and that it had a peremptory and drastic method of acting on those before it. It may well have derived its tone and methods in part from a conscious transfer of those in vogue in the canonical courts or in those of the revived Roman law, with both of which the earlier chancellors were obviously familiar since until the end of the fifteenth century the great majority of them were prelates. The chancellor acted merely upon the "conscience" of litigants by punishing them for contempt of the Great Seal, whose keeper he was, since he could not directly, by virtue of the operation of his decrees, transfer rights recognized by the common law courts. In this way the fiction was maintained that these remained unimpaired despite the interference of the Court of Chancery.

In the fifteenth century, which witnessed the decay of the ancient baronage, a process finally completed by the Wars of the Roses, there emerged the absolutism of the Yorkist and Tudor monarchs, and almost the first effort of the new masters was directed to establishing in England that Roman law which had somewhat perversely become a charter of absolutism on the continent and which had recently recreated there a bureaucratic officialdom converging in the prince.

The attempt failed and was soon abandoned, following the revolt against the Stuart attempt to continue the Tudor tradition. The crown

had destroyed the last vestiges of feudalism and the secular power of the English church only to create a new body of small landowners roughly corresponding to the gentry. As a result of this reorientation the common law courts, King's Bench, Common Pleas, Exchequer, came to represent the established property rights of Englishmen, and the chief instruments of the crown were the Chancery and the Star Chamber, a tribunal of ancient date which was another offshoot of the king's council and which although it exercised some vague civil jurisdiction may be regarded chiefly as the criminal counterpart of the Civil Chancery. But the Star Chamber was abolished, in 1641 the Chancery was temporarily pushed into the background, and the Common Benches were erected into the champions of a government of law as against one of men. In the seventeenth century, however, the vogue of natural law theories revived and strengthened the jurisdiction of the Court of Chancery and put it upon the path which it was to follow in the nineteenth century, when it was mechanized by Eldon and humanized by Romilly and Jessel.

This description of the English judicial system does not take into account such special jurisdictions as the Admiralty Court, the ecclesiastical courts, which were finally abolished in 1857, or such mercantile courts as the Courts of Piepowder or the Courts of the Staple, which disappeared when the law merchant was absorbed into the general law administered by the Common Benches and the Chancery. When Coke wrote his fourth institute he described seventy-four courts which did the work now discharged by three. As long as it was chiefly landed proprietors and rich merchants who appeared before the courts, the difficulties of procedure and the duplication of jurisdictions were not seriously felt. The rise of an industrial society, however, created new and exacting demands for court adjustment arising particularly from the demands of poorer types of litigants for justice. As first attempts at reform may be mentioned the interesting eighteenth century experiment of the courts of requests, which were established to hear small claims not exceeding forty shillings and which had a simplified procedure. When their jurisdiction became too petty as a result of the decline in the value of money they were succeeded by the present English system of county courts. These have no historical connection with the old feudal county courts, being entirely a statutory crea-

tion of 1846. They were especially designed for poorer litigants, and although limited in jurisdiction they make some effort to do justice cheaply as well as effectively.

The general reorganization and unification of the English judicial system was first postponed by the Napoleonic wars and later by the more urgent cry for penal reform. But it gathered momentum during the middle of the nineteenth century and was finally realized in the Judicature Act of 1873, taking effect in 1875. Its purpose was not only to amalgamate the existing courts but also to fuse the principles of common law and equity. A Supreme Court of Judicature was created in two divisions: the High Court of Justice and the Court of Appeal. The High Court was given unlimited jurisdiction and was divided merely for convenience into five divisions: the Chancery Division; the Probate, Divorce and Admiralty Division; the Common Pleas; Exchequer; and Queen's Bench divisions. The latter three were amalgamated into one by order in council in 1881. By the Appellate Jurisdiction Act of 1876 the appellate jurisdiction of the House of Lords was reformed and regularized. A very much needed reform, a system of criminal appeal, which had hitherto existed only in the supervisory jurisdiction of the King's Bench and in the practise of judges in reserving difficult points of criminal law which had been sanctioned by statute in 1848 by the creation of the Court for Crown Cases Reserved, was completed by the establishment of the Court of Criminal Appeal in 1907. But technicalities are still not favored, and a criminal trial in England has acquired many of the qualities of an efficiently despatched transaction which is a grim business for a man under indictment.

On the continent it was in France that the early development of the judicial system was most similar to that of England. The organization of courts in the feudal system after the disruption of Charlemagne's empire was highly complex. There were royal courts, feudal courts, city courts and church courts. Most feudal courts had elaborate divisions, since the feudal princes were themselves suzerains of vassals who had courts of their own and since even the king was duke of France as well as suzerain of the great feudatories and thus conducted two independent kinds of courts. The courts of the feudal lords were as a matter of fact largely usurpations, being in most cases substitutes for those of the Carolingian *Graf* or his

vicar. The distinction between the "high justice" administered by the former and "low justice" administered by the latter corresponded roughly to criminal and civil justice, but it soon ceased to have much practical importance when both were fused, as they were in most seigniorial courts.

The royal justice, on the other hand, soon fused the king's feudal court with his general court. From this *Curia Regis* a number of special courts arose, of which the most notable was the *parlement*, specifically the *Parlement* of Paris, which served as a model for similar institutions in the provinces after the unification of France in the fifteenth century. *Parlement*, which was a court of appeal for royal officers only, successfully claimed after the thirteenth century the right to review many classes of cases from the seigniorial courts. This right of appeal was as powerful an instrument of royal power in France as in England. Equally advantageous to the king were the practise of reserving certain cases solely for him and the right of "prevention" by which the king's judges intervened if the local authorities were in their opinion hesitant or dilatory. In this way local courts were made to possess a delegated authority, but they retained enough of the vestiges of their independent origin to resist the *parlements* a little and keep alive more than a spark of local patriotism.

The *parlement*, which had so potently assisted in the creation of the royal authority, seemed to the crown a greater danger than that of the local courts. Consequently its authority was diminished by the creation of provincial co-ordinate *parlements* and by the formation of new courts, notably the Chamber of Accounts, which took from the *parlement* the very business which had enabled the English Exchequer Chamber to rival the King's Bench. The members of these various courts were in theory royal officers whom we should class as administrators, but there grew up very quickly under the tremendous impetus given by the rapid spread of systematic study of the Roman law a group of professional legists who by the fourteenth century seem to have constituted the *parlement* and from whom came most of those who actively assisted in its proceedings.

One of the effects of that organization of the monarchy which took place in the fifteenth and sixteenth centuries was the simplification of the course of appeal, the elimination of many rival jurisdictions and the introduction of royal

judges even in the cities. Another and apparently contrary effect was the public traffic in judicial offices which were created anew by the king, sold to various persons and dealt with by these persons like estates that were freely transferable and inheritable. It must be admitted that this system was not quite as vicious as it sounds, since some little care was taken as to the general fitness of the grantee. It even made for an independent judiciary, since jurisdiction, being a property right, could not be revoked, nor could the judge be removed.

This system was not abolished until the revolution. The new organization elaborated by the First Republic and finally promulgated by the Napoleonic codes is the one at present in vogue in most of its essential characteristics. The court, usually described as of first instance, is of widest jurisdiction; there is an intermediate court of appeal, a tribunal to settle conflicting claims of jurisdiction and a final highest court (*Cour de Cassation*). An integral feature of the system is the administrative courts, quite independent of the other courts and culminating in the *Conseil d'État*. They were made necessary by the fact that the doctrine of the separation of powers was interpreted in France to mean that the judiciary was powerless to interfere with any of the acts of the administrative authorities.

French courts became part of the governmental administrative machinery. The political development in England, which made the English crown secondary and put the actual government in the hands of an aristocracy of small landholders, allowed the lawyers and judges to grow into something like a separate estate of the realm and to assume an unrivaled independence and power. In France, on the other hand, the crown became practically absolute and the courts, with the exceptions noted, were functionaries in a bureaucratic system. After the revolution this last fact became, if anything, even more apparent. Bureaucracy and a sense of corporate solidarity seem in popular imagination to characterize French courts, although the highest court has more than once given evidence of breadth of view and boldness of action. Despite the fact that litigation is relatively expensive and likely to be protracted the tenacity with which property rights are maintained and defended makes litigation less of a last resort than it is likely to be elsewhere. It cannot be said that there is or has been a lack of confidence in the processes of the courts

in France, and the complaints which are heard there are apparently little more than the almost inevitable resentment of a laity against any control of their lives by professional experts.

In other parts of Europe the development resembled that of France, except that the tendency toward centralization was retarded by the fact that the feudal principalities in Germany and Italy were never organized into a single powerful state before the French Revolution. But one interesting unifying influence in the German states dating from the fifteenth century deserves special mention. This was the organization in 1495 of the Reichskammergericht, or Imperial Chamber of Justice, which endured until 1806. The importance of the emperor's own court had been very much diminished by the Golden Bull of 1356, which exempted the subjects of the electors from appearing before it, and by the fact that the emperor himself was frequently absent from his own dominions. The Reichskammergericht was thus established not as a court of the emperor but as a court of the empire, with a view toward abolishing "cabinet justice." It was given a remarkably wide range of jurisdiction in the field of public law: it had jurisdiction in suits between different territorial sovereigns and it was a supreme appellate court in cases coming from the different territorial courts. It is true that the efficacy of Reichskammergericht was seriously undermined by the creation soon after of another imperial court which often exercised concurrent jurisdiction. Nevertheless, it remained a great influence in the reception of the Roman law in Germany and thus helped to bring a considerable degree of unity into the development of German law.

The nineteenth century compelled a reorganization of courts more or less after the revolutionary pattern, which was faithfully copied in Italy and Spain and recast for her own needs by Germany. In all these states a system of administrative courts was created. The French system also served as a model for most Latin American countries and indeed for a great many nations coming within the range of European influence. It must be noted, however, that neither the Italian nor the German courts had anything like the influence, power or vigor of those of France or England in the period before the Great War, and this has often remained true even where democratization has resulted from post-war developments.

In the United States the early colonial courts

were manned by judges of inferior capacity who were in all cases appointees of the governor or the proprietor and hence acted largely as his agents. In the early colonial legislatures no fine distinction was maintained between legislative and judicial functions. The courts which became established with the final and firm reception of the common law after the revolution were markedly different in respect to both the tenure of the judges and the separation of powers. The judiciary became indeed so independent that it was often beyond the reach of the popular will. The separation of powers was applied in such a way that according to the prevailing theory the courts were supposed to be constitutional bodies who not only could not be deprived of any of their powers as equal and coordinate branches of the government but could not be compelled to assume other than judicial functions. Moreover, it was held that the courts were the arbiters of the extent and nature of the separation of powers. In other words, they received the right, which was then unique, of passing upon the constitutionality of legislative and executive acts. As a result of this power of judicial review the courts came to occupy a particularly important place in the American governmental system.

In their organization American courts have been determined partly by English tradition and partly by special native conditions. To some extent French influence was also felt, since all things French enjoyed great popularity in post-revolutionary America. The force of English example was not particularly fortunate, considering the intricate and multiple nature of the English courts of the period before the judiciary acts. It was offset to some extent, however, by the infiltration of the more rational and formal French ideas of judicial organization. These fitted in well with American necessities; a large and sparsely settled agricultural country needed no complex court system, but it did require one that would bring justice to every man's door. This could be accomplished only by courts of first instance, the basis of whose jurisdiction would be territorial, and by appellate courts, whose supervisory jurisdiction would be general, all the courts finally being arranged in hierarchic gradation. The federal nature of the American Union also encouraged such a judicial structure. If the common law had not underlain American legal institutions, American conditions would have dictated an even greater logical symmetry than they did. Thus, while

it cannot be said that American courts have even now been thoroughly unified, they began to approach this objective long before the English judicature acts. In the less densely populated states the judicial organization is still rather simple. But in the states with many large urban communities the organization of the courts is tending to become complicated. It is true that means of communication and transportation are now so well developed that a greater degree of centralization is feasible than ever before. But against this must be set the need of the cities for many special types of courts.

It is naturally impossible to describe in any detail the present judicial organization of forty-eight different states. But the most typical system is as follows: (1) a highest court of appeal; (2) an intermediate court of appeal; (3) courts of general, original jurisdiction, among which are (a) courts of law, (b) courts of equity, (c) criminal courts and (d) probate, or surrogates', courts; (4) inferior courts of intermediate grade, such as the county courts and municipal courts; and (5) petty courts, such as the court of the justices of the peace in rural districts and the police courts in the cities. The mingling of influence is here obvious. The relation of the courts is to a large extent hierarchic although not unitary. The separate courts of equity are plainly of English origin. But although at first the rule they are now the exception, and separate courts of equity (or Chancery) exist now in only six states: Alabama, Arkansas, Delaware, Mississippi, New Jersey and Tennessee. In many states there are also no separate criminal courts. But where they exist their very names often bear an English stamp, such as Court of Oyer and Terminer and General Gaol Delivery. The courts of general, original jurisdiction, except where there are separate equity courts, are usually endowed with all the powers once possessed by the English Common Bench and the Chancery, subject of course to such modifications as are dictated by American conditions. The probate, or surrogates', courts, which are chiefly entrusted with the management of decedents' estates and actions relating to them, were made necessary by the fact that the English ecclesiastical courts which had first exercised this jurisdiction could not be accepted as models in a republic. The county courts have been particularly important for rural America. They have exercised a far wider jurisdiction than the English county courts, very

often having both civil and criminal jurisdiction in first instance. The municipal courts exist in the cities and help to relieve the congestion of the courts of general civil jurisdiction by taking from them cases involving only moderate amounts (usually one or two thousand dollars). The justices of the peace were obviously also suggested by English example but were given not only a petty criminal but also civil jurisdiction. The justices, however, have not often been of a high caliber, and the excellence of communication has made them in most places so unnecessary that abolition of the office is sought.

The federal judicial power is vested in the Supreme Court of the United States (*q.v.*), which has played a tremendous role in American history as a result of its being the final arbiter of all constitutional questions. The Supreme Court is a constitutional court, owing its existence to article III, section 1, of the constitution, but the inferior federal courts have been shaped by Congress by a series of judiciary acts. The federal courts of general, original jurisdiction are the district courts. Each state constitutes at least one judicial district but some are divided into two, three or four. Each district court is usually presided over by one judge. The district courts have jurisdiction of all cases arising under the constitution or laws of the United States. A peculiarity is the vesting in the federal courts by the constitution of all maritime jurisdiction. They have now also been entrusted with exclusive bankruptcy jurisdiction. The general civil jurisdiction, which is at both law and equity, is usually derived from the diversity of citizenship on the part of litigants, providing the controversy involves more than three thousand dollars. In this way the adjudication by state courts is often escaped when the escape is advantageous to the plaintiff. The federal courts do not always apply the same rules of law as the state courts, and thus a choice of courts involves often a choice of law. The diversity jurisdiction is particularly easy to invoke in corporate reorganization, with the result that the federal courts have come to administer great business interests in receiverships. Above the district courts are the circuit courts of appeal, which were first created in 1891 and of which there are now ten. These courts are intermediate courts of appeal and were established to relieve the Supreme Court of some of its less important burden of appellate jurisdiction. The district and circuit courts are

coordinated by the fact that the circuit judges may sit as district judges.

The federal judicial system is based upon the premise that the federal judicial power cannot be entrusted to the state courts but requires a separate organization of federal courts. Doubtless no other arrangement was possible at the time when the federal judicial system was inaugurated, since the states and the federal government were too jealous of each other to tolerate a unitary system. But a great deal can be urged against it under present conditions of national unity, and it may well be doubted if it would be adopted now if another federal constitutional convention were to meet. Indeed, it is interesting to note that no separate federal system of courts beyond a separate general court of appeal has been established in such federal countries as Germany, Canada and Australia.

The congestion of the courts is a complaint which is made very frequently in connection with the American administration of justice, but it is one that is heard in all countries that have large urban and industrial centers. A common way of meeting it is resort to private arbitration, particularly in commercial cases. Administrative commissions in the United States have also come to exercise many functions which may well be regarded as judicial. It is often suggested that a great deal of the underlying difficulty could be removed by the creation of truly unitary judicial systems in each of the various states, such as exist under the English judicature acts. Part of the English system is a judicial council which surveys the administration of justice and informs itself where additional judges are needed, so that it becomes possible to shift judges from the less congested divisions. This is, however, difficult to do in American courts, which exist independently, and although judicial councils have been adopted in thirteen states (Wisconsin, Massachusetts, Ohio, Oregon, North Carolina, Washington, California, North Dakota, Connecticut, Rhode Island, Kansas, Virginia and Texas) they are largely confined to surveys of judicial administration. The Conference of Senior Circuit Judges established in 1922 has, however, been given powers not only of oversight but also of transferring federal judges from district to district as they are needed.

The problem of congestion can be only imperfectly understood unless all available courts are taken into consideration. But the present review has been necessarily confined to what

may be described as the ordinary court systems. The work of these has at various times and in various countries been supplemented by more specialized types of courts which have received here very little or no mention. Such have been the special administrative, ecclesiastical, commercial or industrial courts. There are also the special types of courts which have appeared particularly in the United States in the last few decades: juvenile courts, domestic relations courts and various types of so-called small claims courts which have been devised to aid poor litigants. The multiplication of special courts for special types of controversies as they arise has been said to be typical of early judicial organization. But in truth they are reappearing under the pressure of modern needs. Nor can the work of modern courts be understood without noting that despite the doctrine of the separation of powers they have in the course of their history acquired and are still acquiring many functions which are really not strictly judicial. The popular conception of a court as an institution for resolving disputes has never been more than partly true. Courts, as has been said, have always had certain administrative functions. Such acts as naturalizing aliens or performing marriage ceremonies are modern instances of such functions. Further, the dispute to be resolved need not be hostile, and in the "non-contentious jurisdiction" of continental courts, in many probate cases, in friendly suits of partition, in the request for advisory and declaratory opinions, there is no dispute in the strict sense. But in these last cases the courts are as much engaged in delimiting rights, actual or potential, as in the ordinary lawsuit.

Courts as institutions have frequently been very unpopular. American courts have often become so because in passing upon the constitutionality of legislation they have come into conflict with the popular will. If it be true that courts in some form are unavoidable, it must be apparent that it is a historical accident whether they shall be few or many, arranged in a hierarchical series, composed of single individuals or groups, dissociated from other agencies or an integral part of them, administered by trained experts or laymen. Any one of these systems may work well with any type of politically or socially organized community. And since it is a historical accident which type shall be used, it is wholly idle to invest a special and familiar type with any degree of sanctity

or to suppose that any particular judicial machinery is essential either for maintaining existing property rights or for modifying them profoundly. The use to which judicial machinery is directed will always depend on the persons who direct it.

In the last analysis a court gains its authority not from the threat of forcible execution which the executive organs of the community announce in aid of its judgments but from an almost general acceptance of these judgments. The end of law is justice, and the courts form the means by which conflicts between citizens are adjusted. The only alternative to the type of court which western civilization has produced—a court which is permanent, wholly or partly differentiated from other governmental functions and administered by a partly segregated class—is a system in which inexperienced men adjudicate conflicts by impressions immediately produced on them. It is extremely unlikely that such impressionistic judgments will be as much in accord with the general communal sense of justice as the technical and systematized adjudications of a formal court.

COURTS, ADMINISTRATIVE. Administrative courts are authorities, outside the ordinary court system, which interpret and apply the laws when acts of public administration are attacked either in formal suits or by other established methods. Administrative adjudication may be the sole function of such authorities, or it may be additional or even incidental to administrative and regulatory functions.

Types of Administrative Courts. Although no two countries have exactly the same administrative court systems, it is possible to divide administrative courts roughly into two main types, the continental and the Anglo-American.

Administrative courts of the continental type are organized into a definite system; arranged in hierarchical order in respect to appeals; generally separated partially or wholly, at least in the higher instances, from the active administration; possessed of a well defined procedure, manned by trained judges and experienced administrators secure in their tenure; and free from the control of the ordinary courts, so that the judgments of the highest appeal instances are final. Certain special administrative courts are sometimes established outside the system.

Administrative courts of the Anglo-American type are not organized into a system. Administrative judicial functions, which may or may not be recognized as such, are often performed by the regular government departments. Special tribunals are also established; these are frequently called boards or commissions. There may be a concentration in the one agency of regulatory, administrative and judicial powers. Cases are often passed upon not by qualified judges and administrators, who cannot normally be dismissed, but by civil servants without judicial training and experience, or even by political appointees, who may be subject to removal at pleasure by the chief executive or by some other administrative officer. There is no general method of procedure nor a definite hierarchy of appeal instances; appeals often lie to the ordinary courts.

The French and the German administrative courts may be taken as the outstanding examples of the continental type. The French system developed historically around the doctrine of the separation of powers, as an agency for protecting

the administration from control by the ordinary courts. The German system developed with the conception of the "legal state" (*Rechtsstaat*) in which all duties should be enforced and rights secured by means of the enactment and enforcement of legal provisions; the administrative court was established as a method for compelling the executive, although free from control by the ordinary courts, to act within the law. The Anglo-American type is not an outgrowth of any philosophy; it is the result of compulsion by circumstances. With the tremendous increase of public functions in the past century, inevitably function after function was given over to a special agency, which might regulate, administer and adjudicate. Occasionally, as with the Court of Customs Appeals, only the judicial function was given to the agency.

The chief administrative tribunals of France are the council of state, the interdepartmental prefectural councils and the councils of litigation in the colonies. Among special administrative tribunals not included in the general system may be mentioned the court of accounts, the superior council on public instruction, the councils of revision, the superior commission on special contributions and the prize council.

Although the Weimar constitution requires the establishment of a national administrative court in Germany, this court has not yet been created. Among the special administrative tribunals established by the Reich are the national insurance office, the national finance court, the national patent office, the higher and the lower courts of arbitration for cases involving employees' insurance, and the national office for public relief agencies. It is in the German states that complete and even elaborate systems are found, each of which has its own special features. In general the states place upon some agency of local administration, such as the county committee in Prussia, the duty of acting as an administrative court of first instance, whereas the higher administrative courts are relatively or entirely independent judicial authorities. Württemberg alone has no such local administrative court.

The chief administrative tribunals in England are the Railway and Canal Commissioners, the Railway Rates Tribunal, the Ministry of Health, the London Building Tribunal, the district auditors, the national health insurance tribunals, the tribunals for unemployment insurance, the Board of Education, the Electricity Control Board and the pensions appeal tribunals; also,

in first instance, the local authority representing these various functions.

The chief federal administrative tribunals in the United States are the Federal Trade Commission; the Interstate Commerce Commission; the Customs Court in first instance and the Court of Customs and Patent Appeals in second instance; the Patent Office, with appeal to the Court of Customs and Patent Appeals; the Board of Tax Appeals; the Court of Claims; the immigration authorities in first instance, with the secretary of labor in second instance in exclusion cases; the food and drug administration; the Board of Tea Appeals; the Federal Power Commission; the registers of district land offices, with appeal to the commissioner of the General Land Office (who acts through an advisory board) and with further appeal to the secretary of the interior; the commissioner of reclamation, the director of the geological survey and the commissioner of Indian affairs, all with appeals to the secretary of the interior; and the Employees' Compensation Commission. In the states the chief administrative tribunals are the public utility regulatory bodies, called variously public service commissions, railroad commissioners, public utility commissions, etc.; the workmen's compensation commissions; the industrial commissions; and certain health authorities.

Jurisdiction. There are two principal types of administrative suits, namely: those which seek to protect a definite right of either an individual or the government (subjective suits); and those which seek to have the law enforced even where no such right is at stake (objective suits).

The jurisdiction of the council of state in France includes both types of suits. The subjective suit of full jurisdiction is a judicial process in which parties are heard, facts as well as law are examined, and justice is done with a view to both the public interest and the individual rights in question. According to the nature of the act giving rise to the suit, it may be annulled or amended if the court considers it illegal, erroneous, inequitable or inadequate.

The objective suit for annulment of an administrative act on the ground of excess of power is quite different. It is an examination into the legality of the act. Although complaint may be made by an individual, he is not a party in a trial. The decision is based on the legal questions involved, and its theoretical purpose is not primarily to do justice to an individual (although it may and usually does have this effect)

but to "protect the objective legal order" by causing the administrative authorities to act within the law. In recent years, however, there has been a decided tendency to disregard this sharp distinction, so that objective and subjective suits are not so clearly differentiated as they formerly were. Only subjective suits may be brought before the lower administrative courts of France.

In most of the German states the jurisdiction of the administrative courts is limited to subjective suits. There are certain exceptions to this rule; thus in Prussia the state administrative authorities may bring suit contesting the validity of certain acts of the local authorities. In exceptional circumstances an individual may bring a similar suit. Ordinarily, however, suits brought by individuals must show a specific rather than a general interest, and a right violated or endangered rather than a mere desire that the law shall be observed by the administrative authorities. As a rule, the jurisdiction of the administrative tribunals in the German states does not include questions of discretion (except sometimes in the lower instance) but only questions of law and fact.

In the United States and England the proof that a personal interest is involved is always required, even where it is claimed that the administrative act in question is illegal. In most instances the administrative tribunals have jurisdiction as to both law and fact, and exercise a good deal of administrative discretion when making their decisions. The appellate administrative tribunals, which are definitely organized as such, usually pass on questions of law and fact, occasionally on questions of law alone. No such limitations bind the ministers or departments which pass upon administrative appeals.

Suits may arise under such circumstances that it is difficult to know whether they appertain to the jurisdiction of the ordinary courts or to that of the administrative courts. Methods have accordingly been devised for meeting this contingency. France has established a tribunal of conflicts, composed of administrative and judicial members. Courts of conflicts are found in most of the German states, and one is anticipated for the Reich when the national administrative court is created. In the United States and England the ordinary courts will pass upon the question whether a given tribunal is acting within its legal jurisdiction.

Procedure. In administrative courts the procedure generally differs more or less from that

in ordinary judicial courts. As a rule, that of the former is more simple, inexpensive and rapid than that of the latter. In many administrative suits attorneys do not appear; there is no jury; a public hearing is not required; the technical rules of evidence are considerably relaxed in order that all relevant facts may be brought out; the administrative judge or experts connected with the tribunal may take an active part in securing and presenting the evidence. Moreover, not only individual rights and claims as they appear in a particular case, but broad considerations of public policy, sometimes going far beyond the issues raised in the suit, may be the acknowledged basis of an administrative decision.

In France procedure varies according to the nature of the suit and the status of the court. Perhaps the simplest procedure is that of the council of state in dealing with the suit asking annulment for excess of power. When the written request for annulment, with supporting documents, reaches the council, investigation is made by a section or subsection. The minister of the department concerned is informed of the question at issue and permitted to make observations and present memoranda. There is no public hearing. The council makes its decision on the basis of all the materials presented and its own investigations. According to the subject and importance of the case, any decision reached may be made by a section, a subsection or the full assembly of the council. All decisions are announced in its name, however, and all are equally valid. A more complicated procedure, with attorneys and the possibility of an oral hearing, is employed for suits of full jurisdiction.

Procedure before the administrative courts in Germany is based in general upon the provisions of the national code of civil procedure, although differences appear from state to state. Departures from this code are chiefly due to the special needs of a court established for a special function, or to the fact that in many administrative suits the public interest is in question. Not only are both sides heard, as in the ordinary civil process, but also the representatives of the public interest. All states guarantee publicity and verbal discussions, with certain exceptions and limitations. The administrative court may undertake any investigations that will throw light on the matter at issue. The decision is based upon all facts that are either brought out in the testimony or developed as the result of the investigation, including considerations of public interest. Furthermore, as in France, the deci-

sion may go beyond the requests of the complaint by which the suit was instituted, with the purpose of bringing about an equitable and socially desirable situation.

In England there are no general rules of procedure for administrative suits. The few administrative tribunals which are established as such have varying procedures, generally including notice and hearing. Leading decisions on appeals (*Board of Education v. Rice*, 1911 A.C. 179; *Local Government Board v. Arlidge*, 1915 A.C. 120) show a tendency on the part of the judicial authorities to permit informal procedure and to leave the administrative agency making the decision as free as possible to develop its own methods, but to require that each party to a case be given an opportunity to present his side of the matter, either orally or in writing, and that decisions be reached "in a judicial temper."

Procedure in the United States is somewhat more definitely developed, owing partly to the fact that a number of administrative tribunals are clearly recognized and established as such, and partly to the enforcement by the ordinary courts of their conception of "due process of law." A tendency still exists, however, to regard as routine administrative decisions many acts which are by nature administrative judicial decisions—notably decisions of health, education and immigration authorities—and to construe due process in connection with these acts so broadly that occasionally important rights of liberty and property may be withdrawn from individuals without any opportunity for a true suit to be opened or a judgment given, as in the *Ju Toy* case [*U. S. v. Ju Toy*, 198 U. S. 253 (1905)]. It should be acknowledged that there is much confusion and inconsistency in the attitude of the courts, and it is necessary to mention a contradictory tendency on their part to interfere somewhat strangely at times with administrative acts (such as the O'Fallon order of the Interstate Commerce Commission) under color of merely assuring due process. Despite the difficulties to which it has given rise, the conception of due process is unquestionably an important factor in the development of definite and adequate administrative judicial procedure. This procedure often tends to approximate that of the ordinary courts, not only because of the due process requirement, but also because of the long tradition that tribunals of any sort ought to give hearings, call witnesses and decide on the basis of the evidence presented. It is sometimes

asserted that there is too much insistence upon decisions based on the facts presented by the parties, and too little use of other relevant materials which could and should be obtained by the administrative tribunals in order that their judgments might be fully informed, particularly as to the public interests involved.

Recourses. In France it is nearly always possible to appeal to the council of state from the decisions of the interdepartmental prefectural councils and the councils of litigation in the colonies. This is not universally true; for example, suits concerning public accounts go on appeal to the court of accounts. Nevertheless, every special administrative court in France, even though its decisions are final within its own field of jurisdiction, is brought under the council of state as judge in cassation. It may therefore be said that the council of state affords recourse against the judgments of all administrative tribunals. Furthermore, it affords recourse against acts of departments and ministers when application has been made to them to right a wrong and they have refused to do so. Finally, it offers certain recourses against its own judgments, including opposition and review.

In Germany the number and the nature of the remedies against the decisions of administrative courts vary greatly in the different states. In Württemberg, where there is only one such court, its decisions of course are final. In Prussia the legal remedies available are of two sorts, the ordinary and the extraordinary. The ordinary recourses include the petition, the review and the appeal or formal complaint. The extraordinary remedies consist of remanding the case to the previous status, and the retrial.

There is no well organized system of recourses against the decisions of administrative tribunals in England. Appeals from the original tribunals to the higher authority, although judicial in the sense that legal questions are involved, are generally treated as little more than administrative appeals, instead of actual suits on administrative questions. Often a government department or other administrative agency is an appellate authority, particularly the Ministry of Health, the Ministry of Labour and the Board of Education. In some instances recourse may be taken to a referee, or a board or court of referees, or to an umpire. For the great majority of cases there is no appeal to the judicial courts except on the question of jurisdiction. When an appeal does lie to the ordinary courts, as a rule they will take cognizance only of questions of law.

Very seldom is there an appeal to more than one instance.

In the United States there is usually recourse to the ordinary courts on questions of both law and fact, sometimes of law alone. In connection with some of the most important federal administrative courts, such as the Federal Trade Commission, the Interstate Commerce Commission, the Board of General Appraisers and the Board of Tax Appeals, methods are provided for judicial examination, with a further possibility of recourse to the Supreme Court through certiorari. In some cases, however, where an administrative authority is exercising powers judicial in nature, no appeal is permitted to the ordinary courts, but only to a higher administrative authority or the head of a government department.

The Place of Administrative Courts in the Governmental System. Administrative courts not only relieve the ordinary courts of a great bulk of work, but also serve purposes foreign to the latter. One of these is the decision of cases according to law, but by means of a particular set of values, in which the public interest is emphasized and the old individualistic common law conceptions of legal relationships are minimized, at the same time that the rights of the individual are protected by the fact that the administration is compelled to act within the law. The informal and inexpensive procedure before most administrative courts, and the possibility of specialization either in separate courts or in chambers, are generally considered very desirable. Another valuable feature is the securing of information relevant to a suit through agencies connected with the administrative courts, thus enabling the decisions to be made on the basis of more complete information than is likely to be obtained from partisan testimony. In the continental system the possibility of securing the annulment of illegal administrative acts and orders avoids the frequent necessity of disregarding them with a view toward subsequently defending this course when the administrative authorities bring suit to compel obedience—a situation which must inevitably breed disrespect for law and a spirit of defiance toward government. The continental administrative courts, generally possessing their own appellate instances beyond the control of the ordinary courts, maintain a separation between the administrative and the judicial powers. Although the ordinary courts are unable to control the administration as they do in the United States

and to a considerable extent in England, legal administrative action is compelled, and individual rights are secured, by an adequate trial before a competent tribunal. The weight of expert opinion considers the continental system more satisfactory than the separate administrative courts, practically always subject in certain respects to the judicial courts, which are found in England and the United States. There is no doubt that administrative courts of some kind are a necessary and increasingly important part of modern governmental machinery.

COURTS, COMMERCIAL. Commercial courts may be broadly defined as courts composed of persons with special knowledge of trade and commerce to adjudicate disputes arising between parties to commercial transactions. They connote a specialized judiciary, a special jurisdiction as to causes and a non-technical procedure. More particularly, they should be distinguished from the position of ordinary courts having special calendars, chambers or lists for commercial cases.

There are evidences of the prototype of such courts in the judicial organization of ancient Athens. Upon the passing of the senate of the Areopagus and the rise of the dicasts, or popular courts, the supervising magistrates (the thesmothetes) appear to have specially arranged commercial cases for summary trial before particular dicasts.

The Roman system of judicial administration does not appear to have provided separate commercial tribunals. Trade regulations were diffused with other matters in the *Corpus juris* and were adjudged by the ordinary courts.

Courts by and for merchants assume an institutional identity most clearly in the Middle Ages. The beginnings of their development in this era should be credited to the independent cities of Italy. Following the routes of trade the development of these courts spread over the remainder of continental Europe. By the middle of the fourteenth century their development had culminated in governmental recognition in Italy and Spain and they were functioning in connection with authoritative commercial laws. Their jurisdiction was virtually exclusive of the ordinary courts in causes relating to trade. Like recognition was accorded such courts in France after a protracted struggle lasting into the sixteenth century and in Germany near the close of the seventeenth century.

Commercial courts are also found in the history of England. Piepowder courts, as they were called, appeared there, as on the continent, in connection with the mercantile fairs. As on the continent also these fairs and their courts were located at the trading centers where merchants met to transact business. But the piepowder courts of England failed to gain extended state recognition in competition with the king's courts. This is true notwithstanding

an occasional royal edict that merchants should have prompt justice *secundum legem mercatorum* and certain charter grants to trading companies of a jurisdiction over trade disputes between members. Before the close of the sixteenth century it was clear that England's commercial law was to be made by the regular courts, jealous of their power and prestige if not of their fees. Before the close of the seventeenth century absorption by these courts was completed. Uncritical Anglo-American historians glorify this as an instance of the genius of the common law.

The rise of commercial courts on the continent, first in Italy and Spain and later in France and Germany, was due in part to the development of political and economic power of the merchant class. Mercantile guild organization, existing for both aggressive and protective purposes, comprehended a separate and specially adapted plan of judicial administration. Such administration was a natural incident of the more general demand for self-government which prompted the guild movement. Again, as extramunicipal trade developed, political boundary lines failed to delimit trade and the need for a cosmopolitan commercial law became an immediate consideration of trade and commerce. Lastly, an inexpensive, expeditious and non-technical judicial procedure was inevitably demanded as a relief from the exasperating technicality of the civil law. Indeed, it is particularly significant in this connection to observe that the need for commercial courts in Germany appears not to have been felt until the so-called reception of Roman law with its dilatory tactics of practise.

Commercial courts were absorbed in some of the continental countries by a process not unlike that which took place earlier in England. In Italy and Spain, their original home, these courts were similarly displaced during the last third of the nineteenth century and in Germany after the formation of the empire. The separate identity and state recognition of these courts in connection with a commercial code still obtain in France and Belgium and in several countries in Latin America (Argentina, Brazil, Guatemala, Panama, Santo Domingo and Uruguay). The more important details of the French system are suggestive of the systems of the other countries where commercial courts still exist.

Most of the French tribunals of commerce are composed of four business men elected to

office for a term of two years. Candidates for the office must be at least thirty years of age and must have had at least five years' experience as a licensed merchant, broker, corporation manager or sea captain. Their electors must be similarly qualified. Provision is also made for the assistance of arbitrators and of experts such as accountants and appraisers. The judges serve without pay.

At present there are some two hundred tribunals of commerce in France functioning under the Ministry of Justice. The Paris tribunal, with jurisdiction for the Department of the Seine, is the most important with respect to size and the volume of cases dealt with. This tribunal consists of sixty-seven judges acting in eleven chambers and handles about one half of the commercial cases of France.

Under the French system cases are commenced by citation upon the defendant. The case is then docketed and called within a few days. The Paris tribunal convenes twice weekly for calling the docket and reporting previous judgments. There are no formal trials; lawyers of the ordinary courts are excluded. The cause is assigned to one of the judges deemed best qualified for the type of question involved. He investigates evidence, interrogates the parties and witnesses and examines the reports of any special assistant to whom matters may have been referred. This judge renders a judgment on the facts and with reference to the commercial code and reports his judgment to the court. At least two other judges must concur. The judgment is ordinarily reported within a month after the citation. It becomes final after two months in absence of appeal. Judgments of the tribunal are enforced by execution as in the ordinary courts in the absence of appeal. Appeals may be had to an ordinary court of appeal if the matter involved is worth more than 1500 francs.

The French commercial tribunals are credited with the disposition of 200,000 cases annually. The following summary of cases in the Paris tribunal is reported by the United States Department of Commerce in the special circular cited below, as follows:

"The statistics for the Tribunal of Commerce of the Seine, which cover about half the entire volume of commerce litigation in France, show that for the calendar year 1929 a total of 105,584 cases were dealt with judicially. This was an average of 9,598 for each of the eleven chambers and 1,575 for each of the 67 judges.

"The volume of detailed work of the judges was reduced, however, by the reference of 13,888 cases to arbitrators or professional syndicates, the conciliation of 4,256, the withdrawal or merging of 10,582 and the judging by default of 51,293. Deduction of these categories leaves 25,565 cases which were adjudicated on their merits, or an average of 381 for each judge.

"Of the 76,858 cases judged by default or after full inquiry and hearing, 26,792 were in last resort, as they involved 1,500 francs or less, while 50,066 were in first resort, involving more than 1,500 francs.

"During the calendar year 1929 new cases filed with the Paris commerce tribunal numbered 77,033, while 20,249 old cases were reopened. The new cases exceeded by 9,046 the number filed in 1928. At the close of 1929 there were 5,971 cases remaining on the docket. Of these, 3,331 were filed in the last two months of the year and only 572 had been instituted as far back as July, 1929. From these figures it is evident that, despite the great and increasing number of cases filed, the tribunal is equal to the recognized need for promptness and despatch in commercial litigation."

In contrast to the generally unfavorable attitude toward the ordinary courts the French tribunals of commerce are commended for the ability of the judges as manifested by their decisions upon technical questions of commerce. Their decisions are arrived at speedily by a non-formal procedure and with a minimum of delay and costs. The commercial court accomplishes as intelligent and expeditious a disposition of commercial causes by qualified experts as does the practise of commercial arbitration by independent trade groups. It also possesses the advantages of simplicity of procedure and practise under the direct authority of state institutions.

Many recent reforms in procedure and practise of the ordinary courts in the United States are commendable, but a backlog of traditionalism remains because judges and lawyers are legalistic in training and methodology. Consequently provisions for the reference of causes to a short or commercial calendar of an ordinary court (and the same is true of the commercial lists in England) are for the most part rusting for want of use. Judges, lawyers, legalism, costs and delays are responsible.

That it is ideal to have specially qualified judges sitting with expert assistants to inquire into, investigate and decide the highly tech-

nical and varied disputes of modern business promptly and inexpensively, there can be little question. Personnel, training and traditionalism of the bench and bar, however, permit little hope of an early realization of any such ideal in the United States. The modern practise of commercial arbitration has thus far afforded the most practicable relief.

COURTS, INDUSTRIAL. Industrial courts are special courts for adjudicating disputes in labor relations. They may exist to deal either with collective trade disputes or with individual disputes between employers and employees or for both purposes. In so far as industrial courts are chiefly courts of arbitration or conciliation

they have been described in the articles on these subjects. The industrial courts to be now treated are the special occupational courts of continental Europe, which exist primarily to deal with individual disputes between employer and employee or between employees, based upon individual or collective contracts. It is true, however, that these European industrial courts have often also exercised functions of arbitration and conciliation.

While the present European industrial courts have no historical continuity with the mediæval guild courts they carry on in a sense the same tradition. The modern courts derive from the establishment in 1806 of the French system of *conseils de prud'hommes*, which were themselves founded upon prerevolutionary experiments such as the Tribunal Commun in Lyons. Although the system of industrial courts thus originated in France they received their most extensive development and became most prominent in Germany, which in recent years has introduced a plenary system of labor jurisdiction.

In the Napoleonic period the *conseils de prud'hommes* became established in the Rhine provinces. There had also developed in Prussia, particularly in Berlin, a number of factory courts. The *Gewerbeordnung* (industrial code) of 1869 for Prussia established a general system of industrial courts. The system of *Gewerbegerichte*, which functioned until recently, was established under the empire by the law of 1891 as amended by the law of 1901. Such courts were made compulsory in cities of over 20,000. The types of suits they usually handled involved arrears of wages and compensation for discharges without notice. The limit of jurisdiction was one hundred marks and appeal lay to the *Landgericht*, the ordinary district court. The *Gewerbegerichte* also acted as boards of arbitration and were popular with the workers. Since the *Gewerbegerichte*, as their names imply, took cognizance only of labor in industry, there was agitation for the extension of their benefits to other types of workers, which led in 1904 to the establishment of the so-called *Kaufmannsgerichte* to deal with labor cases arising from mercantile pursuits. The name *Kaufmannsgerichte* has proved confusing since it implies, contrary to the fact, that the court might have jurisdiction over civil suits between merchants arising from commercial transactions. Such commercial courts did not then exist in Germany; there were only special commercial divisions in the *Landgericht*.

The present labor courts rest upon the law of December 23, 1926, which went into effect in July, 1927. The old system has been changed in many radical respects. The former courts were established by the various municipalities. The new ones are part of a nationally organized system of labor justice. While the old courts were only of first instance, and appeal lay to the ordinary courts, the new system has also established intermediary and final appellate courts. There are local labor courts, regional labor courts and finally the *Reichsarbeitsgericht*, the national appellate court. As the change of name of *Gewerbegerichte* to *Arbeitsgerichte* indicates, the scope of occupational jurisdiction has been widened to its greatest possible extent. Provision is now made not only for industrial and mercantile workers but for railroad employees, agricultural workers and domestic servants. Special mining courts which had existed since 1891 were abolished. Separate chambers for particular industries, however, still exist in some of the district courts.

The competence of the new labor courts extends to all individual disputes between employers and employees, to disputes between employees in the same industry and to civil disputes arising out of collective labor agreements. The courts no longer participate in the formation of such agreements. In addition they exercise a kind of administrative jurisdiction in matters pertaining to the organization of the works councils. Nevertheless, the handling of collective disputes has been entrusted to other authorities constituting boards of arbitration.

As they are now organized the district and regional labor courts are constituted by one professional judge and two lay assessors, one representing the employers and the other the employees. The reduction of the number of the assessors from the four under the old system to two has put greater responsibility upon the judge. In cases involving collective agreements, however, there are still four assessors. The national labor court is organized as a council consisting of three members of the regular national supreme court (the *Reichsgericht*) and two associates appointed for their expert knowledge. This participation of lay advisers, representing employers and employees equally, with professional judges has been a distinguishing characteristic of both the old and new German labor courts. A consistent interpretation of the law is thus insured as it is also by the system of intermediary and final appeal, resulting in a

unity that has hitherto been lacking. The new system of labor justice has already justified itself in an extraordinary manner in the few years of its existence.

The systems of labor courts which have been based upon the French *conseils de prud'hommes* may be described essentially as courts of industrial experts organized by the state at need, in contrast to the German idea of an industrial court as a civil court with a special jurisdiction. The decrees by which they have been organized usually fixed the occupational range of their jurisdiction, but mercantile as well as industrial pursuits have been included. They have thus not been based upon any inclusive concept of labor jurisdiction, which, moreover, has remained confined to proceedings at first instance. The systems of Belgium, Portugal and parts of Switzerland are based upon the French, as were the Spanish and Italian until recent years.

The present French *conseils de prud'hommes* decide to the exclusion of the *juges de paix* in cases arising from individual or group disputes as to the terms of a contract of labor in trade and industry where the amount in industry does not exceed two thousand francs (law of 1907, as amended by laws of 1919 and 1920, as codified in the fourth book of the *Code du travail*). They also decide in cases of claims for damages arising out of collective trade union agreements. The *conseil de prud'hommes* is divided into two sections, the first called a *bureau de conciliation*, which makes a preliminary attempt to bring the parties to a settlement by conciliation, and the second called a *bureau de jugement*, where the actual trial takes place when the first stage of the proceedings fails. To the former, employers and employees each elect one representative; to the latter, they send other lay members in equal numbers. *Juges de paix* are only exceptionally assigned in cases where the lay judges disagree, so that the secretary of the court, being the only professionally trained member, exerts a commanding influence. The ordinary tribunals function as courts of appeal.

Although other countries have borrowed chiefly from French or German models, the influences have often been mixed and many variations are to be found. The Belgian *conseils de prud'hommes* were reorganized by the law of July 9, 1926. The Portuguese industrial courts, called *tribunai de arbitros-avindores*, rest upon the law of August 14, 1889. In German Austria the present *Gewerbegerichte* are organized under the law of 1922, as amended in 1925, preceded

by the laws of 1869, 1896 and 1910, which had narrower industrial application; but courts are to be found only in nine cities. In Czechoslovakia there is no uniform system: in the former Austrian region the limited Austrian system of 1910 applies, but in Carpathian Russia and Slovakia there are no industrial courts at all. Similarly, Switzerland has not achieved juristic unity; the regulation of industrial courts is left to the individual cantons, and twelve out of twenty-five of these have often placed no restrictions on the types of courts that may be erected in various cities. Certain procedural details, however, are prescribed by the federal Factory Law of 1914; the courts that exist derive in part from the *conseils de prud'hommes*, but the later influence has been increasingly Germanic.

The courts of the foregoing countries when compared as to competence, constitution and right of appeal often show divergences from their models. (1) As to competence: although the Belgian courts are supposed to have upon principle a broad general jurisdiction in all labor relations, the exceptions are so numerous that it is very similar to that of the French; the limit of competence, moreover, is as high as twenty-four thousand francs. The Portuguese courts, which are established by the state at need, are available to salaried employees as well as industrial workers. The Austrian courts, although called *Gewerbegerichte*, exercise comprehensive labor jurisdiction except that agricultural, forest and domestic workers are excluded. (2) As to constitution: again, in the Belgian courts in contradistinction to the French rule the elected lay judges are assisted in the *bureaux de jugement* by an *assesseur juridique*, but he has no vote except in case of a tie. The lay judges are generally chosen upon the principle of employer-employee representation on the basis of parity. (3) As to the right of appeal: while it lies most often to the ordinary courts, in Belgium *conseils de prud'hommes d'appel* exist, and in Portugal appeal may be taken to the tribunal of commerce, as was at one time the case in France.

In Czechoslovakia plans have been mooted in 1925, 1926 and finally in 1930 for a unified and comprehensive system of labor courts. The 1930 plan calls for labor courts under the presidency of professional judges in all localities of more than 10,000 inhabitants, and appeals are to run to district labor courts. The social movements of the post-war period have, indeed, wrought many changes in the constitutions of the indus-

trial courts. While in most countries they have simply undergone an organic evolution, in the three states that may be described as ruled by dictatorships, Spain, Italy and Russia, the changes have been more far reaching. All three of these countries have special systems of labor jurisdiction but none of them can be said to have complete systems of labor courts.

Spain, which under its law of 1912 had a system of industrial courts based upon the *conseils de prud'hommes*, created a new system in 1926. The labor jurisdiction is general except that domestic servants are excluded. Even in districts where labor courts are not warranted the ordinary courts are directed to employ a special procedure in labor matters. The labor courts are presided over by a professional judge, and the lay trade representatives act as a sort of special jury. Cassation is allowed to the courts of highest instance in cases of sufficient importance. Italy in 1928 abolished the old *collegi dei probi viri*, which was derived from the French and first established in 1893, and the more recent *commissioni arbitrali provinciali* for salaried employees established in 1923. The jurisdiction of these courts has been transferred to the ordinary courts, which, however, may act only in consultation with two associate judges representing respectively employers and employees. The court of appeal for individual labor disputes is the labor court (*magistrato del lavoro*), a council of the court of appeals strengthened by two appointed lay judges, who must be graduates in law but not necessarily employers or employees. This council is also a court of first instance for collective disputes and an arbitration board. Labor jurisdiction in the Soviet Union is naturally closely bound up with the ordinary jurisdiction. In economic centers and the seats of courts of second instance labor sessions, that is to say, meetings of the people's court, may be ordered for the trial of labor disputes. They deal with individual and collective disputes as well as industrial crimes, unless a court of arbitration has already taken cognizance of them. The judge in the labor sessions need not be a trained jurist, and he is assigned two associates, one appointed by the regional federation of trade unions and the other by the governmental executive committee on the nomination of the local economic council. Cassation lies from the work sessions to the highest courts.

COURTS, JUVENILE. See JUVENILE COURTS.

COURTSHIP may be defined to include all forms of behavior tending to stimulate sex excitement and sex activity in the desired mate. In the animal world these comprise display, song and dance and other antics, pursuit, the discharge of perfumes and in some cases also the offer of prey or other exciting objects. The details vary enormously from species to species. Courtship is not found in plants, and in the animal world it is confined to the vertebrates, the mollusks and the arthropods. The distribution is, however, very uneven within these orders. Courtship is most conspicuous in birds but comparatively little known in mammals. The biological significance of the phenomena classed under animal courtship is still much disputed and its correct interpretation must await fuller knowledge of the sex life of animals and, in particular, fuller insight into the role of sexual selection. It seems probable that there is a correlation between sexual ardor and such sex characters as coloration and ornamentation, since both are influenced by the same hormones. But whether these sex characters lead to preferential mating and whether this results in an intensification of these characters is doubtful.

Among humans biological aspects of court-

ship are regulated by cultural traditions which modify, inhibit and stimulate the physiological mechanisms. Diversified cultural tabus associated with chastity, sexual asceticism and etiquette circumscribe and determine the nature of courtship relationships. There are wide divergences among different peoples and in different historical periods in the types of behavior permitted or prescribed during the courtship period.

Dance and music are a frequent means of stimulating sexual excitement during courtship. Fighting among suitors is not uncommon as part of the procedure of courting, and tournaments or trials of strength are often among the preliminaries of the marriage ceremonials. Erotic games and love magic are widely used courtship devices. That ornamentation serves as a sexual allurements is *prima facie* probable. Both primitive and modern peoples often give desire for sexual attractiveness as the reason for personal decoration, although other factors are also involved.

The active part in wooing is taken generally by the male, but there are numerous exceptions to this rule in all parts of the world. It has been suggested that the practise of the female taking the initiative in wooing is an aspect of, and is more in harmony with, the matrilineal system of kinship, but this alleged association is not substantiated by an analysis of the evidence.

The phenomena of courtship are not intelligible unless it is remembered that marriage, to which the courtship is preliminary, is a relationship affecting not only the young man and woman but also their families. Among many peoples marriage is a matter of arrangement between the families, although this does not always mean that the girl's wishes are ignored, for even where child betrothal is practised there are often methods whereby the girl may evade marriage with the man to whom she is betrothed. The period of courtship provides an opportunity for the families to settle the economic problems that arise between them as well as to test the suitor's adaptability and general desirability. This is particularly obvious among peoples with whom service in the girl's family is the normal method of obtaining a wife. Among some Siberian tribes the parents of the girl may send the man away even after five or ten years of such service. Apart from the institution of marriage by service prolonged periods of courtship and premarital love making are not uncommon even in primitive societies. The importance of delay and hesi-

tation is indicated in the many cases in which resistance by the bride forms a part of the ceremonies connected with betrothal or marriage. In some cases a show of resistance is made both by the women and the men as, for example, among the Mpfumo people, where visits by the bridegroom and his friends to the bride's village and return visits by the girl and her friends constitute a necessary part of courtship and where on both occasions there is much show of hesitation to enter the village and of reluctance to accept food. Among the Chuckchee the wife is withheld from the adopted son-in-law for several years "to make his attachment stronger." A similar practise is that which is found among many European peasants of spending continent nights in the arms of the fiancée. In modern industrial countries the period of courtship is usually protracted by economic considerations involving the ability of the man to support the woman, although with the entrance of women into industry the factor is not everywhere as potent as formerly.

It has been urged from the biological point of view that courtship is rendered necessary by female coyness, which is interpreted as a temporary reluctance serving to incite the male to pursuit. According to Havelock Ellis the object of courtship, of the mutual approximation and caresses of two persons, is to create the state of sexual tumescence. Westernmark doubts whether the sexual impulses are so weak as to need this additional stimulus and suggests that the prolongation of excitement has the effect of increasing the secretions of the sexual glands and thus of facilitating fecundation. Other authorities are of the opinion that the reluctance serves to discourage the less ardent and energetic males—an explanation to which some countenance is given by the numerous cases in which endurance tests and fights form part of the procedure of courtship. Two additional reasons of a psychological and sociological nature may be given. It seems generally agreed that the development of sexual attachment is relatively slow in women but when once aroused is more enduring, while in man the process of growth is more rapid and the duration generally briefer. The function of delay and resistance would seem to be to allow time for the transformation of the sudden and momentary excitement of the male into a sentiment of love and thus to fuse the sex impulses proper with the social feelings and other elements of tenderness and affection. Secondly, it is widely held that in the sexual impulses of the

male there are present aggressive and destructive components. The period of courtship and especially the delay and control it involves, while perhaps acting as stimulants, also tend to moderate and tame the fierceness of male sexuality. Courtship, in short, in giving time for the sentiment of love to mature and thus to absorb the sex impulses into a wider and more stable system tends to render the sex relationship more enduring and pervasive, to equalize the differential responsiveness to sex stimuli as between men and women and in general to civilize love.

COUSIN, VICTOR (1792-1867), French philosopher, founder of the eclectic school. Cousin taught literature and later philosophy at the école Normale. He was an erudite historian of philosophy and made many scholarly contributions in this field. His own thought was a combination of diverse elements. As a disciple of Royer-Collard, Cousin appealed to the anti-metaphysical common sense of the Scotch philosophers. Later he turned to German romanticism and was the first to introduce Hegel's work into France. Under these influences he worked out spiritualistic philosophy looking to enfranchisement by means of political action independent of daily contingencies. "We have

wanted too long to be free with the ethics of slaves," he told his students in 1815. Although he was suspended from the Sorbonne by the restoration in 1821 and imprisoned for six months in Germany on suspicion of Carbonarism he was in no sense a radical. He stood for the middle way between Left and Right, for the constitutional monarchy and free speech, free press and free worship. He warned that absolutism must lead to terror and viewed constitutional monarchy as the happy synthesis. He defended philosophy against clerical attacks and yet used his power to subject the teaching of philosophy in the secondary schools to clerical authority. He participated in the antiliberal campaign in 1848, writing in *Justice et Charité* (Paris 1848; tr. by W. Hazlitt, London 1848) an academy pamphlet against the revolutionary notions of equality and the right to employment or assistance, and was violently attacked both by the clerical-royalist group and the republicans. In his later years he attempted to develop further his philosophy of compromise, sacrificing the best of his early theories to minimize church opposition. His chief service was that he infused into French universities the breath of liberty which made possible the work of Jules Lachelier, Émile Boutroux and Henri Bergson.

LÉON BRUNSCHWIG

Important works: *Du vrai, du beau, et du bien* (Paris 1836, 3rd ed. 1853), tr. by O. W. Wight (Edinburgh 1854); *Cours de l'histoire de la philosophie moderne* (Paris 1828; 2nd ed. in 8 vols., 1846-47), tr. by O. W. Wight, 2 vols. (Edinburgh 1852); *Cours de l'histoire de philosophie*, 2 vols. (Paris 1829), a chapter of which was translated by C. S. Henry as "Elements of Psychology" in his *Critical Examination of Locke's Essay* (4th ed. New York 1856).

Consult: Boas, G., *French Philosophies of the Romantic Period* (Baltimore 1925) ch. v; Dubois, L. P., *Cousin, Jouffroy, Damiron* (Paris 1902); Lévy-Bruhl, L., *History of Modern Philosophy in France*, tr. from the French by G. Coblenz (Chicago 1899) p. 330-51; Janet, Paul, *Victor Cousin et son oeuvre* (Paris 1885); Simon, Jules, *Victor Cousin* (Paris 1887); Barthélemy-Saint-Hilaire, J., *M. Victor Cousin: sa vie et sa correspondance*, 3 vols. (Paris 1895).

COUTTS, THOMAS (1735-1822), English banker. In 1761 Coutts joined his brother James as partner in an old established London banking house, and he became its head in 1775. He stands out as the most successful example of the old fashioned family banker. He was personally acquainted with his customers and extended his clientele by personal introductions. New customers, who knew nothing about the resource

of his bank, were attracted by his personal shrewdness and integrity. His investments were mainly personal loans. He fully understood the value of what is now called "service" and transacted all manner of business for customers remote from London. He undertook confidential missions for King George III, straightened the tangled finances of the royal princes and was consulted by leading statesmen of all parties. The greatest names in contemporary British history were in his books, and the French Revolution brought to his bank royal and noble families of the continent. Starting with a capital of £4000 he died worth £900,000 and one of the most influential men in England. His granddaughter, Angela Burdett (1814-1906), who inherited his fortune in 1837, became famous as Baroness Burdett-Coutts for her widespread benevolence. The management of the bank remained in the hands of the young men chosen by Coutts as his partners and their descendants, joined later by descendants of Coutts' daughters. This hereditary connection has contributed to the perpetuation in Coutts' bank of old banking principles and customs side by side with modernized methods.

COVARRUBIAS Y LEIVA, DIEGO (1512-77), Spanish theologian and jurist. Covarrubias was educated at Salamanca and the Colegio Mayor of Oviedo. At an early age he was appointed to the chair of canon law at Salamanca. Subsequently he was professor at Oviedo, judge in Burgos, counselor at Granada and bishop of Ciudad Rodrigo and later of Segovia. Just before his death he was nominated to the bishopric of Cuenca. He was also active in affairs of state, where his legal gifts were of great service; in 1572 he was appointed to the Council of Castile and in 1574 to its presidency.

Covarrubias wrote a number of treatises on criminal law, domestic relations, international law and other legal topics. He was also the author of *Veterum numismatum collatio* (Salamanca 1573), a work valuable for the study of the monetary system of Spain. In it Covarrubias discussed the authority of the king in all matters pertaining to money and interest.

With the foundation of the San Clemente College at Bologna in 1367 a new impetus was given to that school of Spanish legal philosophy which since the thirteenth century had been attempting to reconcile Roman and Spanish theories of law. A characteristic example of this attempt is the Gregorio López edition of *Las siete partidas* (Salamanca 1555), in which the multitude of references to Azo, Gratian and St. Thomas obscured the essential distinction between the two schools. Covarrubias was the genius of the López school, and his legal advice, based on the absolutist ideas of Roman law rather than on Christian theories, had the effect of strengthening the position of the king. This was of great importance to the development of monarchy in Spain, since Philip II followed legal formulae with meticulous care. Despite his Roman interpretations of monarchical government, however, Covarrubias held the traditional view that the authority of the king should be limited by the scholastic definitions of the interests of the people.

Covarrubias was a constructive theologian and took part from 1560 to 1564 in all the important sessions of the Council of Trent, which discussed the sacraments, the sacrifice of the mass and the disciplinary reforms. His analytic thinking, his intuitive grasp of the essentials of dogmatic definitions and his power to express these in clear and simple Latin won him a place on Cardinal Buoncompagni's committee to edit the decrees. He remained faithful, however, to the Spanish sovereign and on points of discipline defended the privileges which the Spanish kings demanded. His expositions show the influence of the Roman legal concepts on the questions of patronage and the adjustment of relations between church and state in Spain.

The best collection of Covarrubias' works was issued in 1762 (2 vols., Geneva).

MARIE R. MADDEN

Consult: Vales, Faide, Javier, in *Fueroconsultos españoles*, 3 vols. (Madrid 1911-14) vol. i, p. 43-50; Hurter, Hugo, *Nomenclator literarius recentioris theologiae catholicae*, 6 vols. (3rd ed. Innsbruck 1903-13) vol. i, p. 38-39, for bibliography.

COWDRAY, FIRST VISCOUNT, WEETMAN DICKINSON PEARSON (1856-1927), British capitalist. At an early age he entered the contracting firm of S. Pearson and Son and extended its field to include the international promotion, construction and operation of railroads, utilities and public works. He was a

Liberal member of Parliament from 1895 to 1910, when he was raised to the peerage. In 1917-18 he was president of the Air Board.

Cowdray was a significant figure in the Anglo-American "oil war." He broke the virtual monopoly of American oil interests in Mexico but was prevented by diplomatic pressure from obtaining concessions in Colombia and elsewhere in the Panama Canal region. He tried unsuccessfully to unite British oil companies throughout the world into one British government company.

In 1889 he went to Mexico to build a canal and later the Tehuantepec railroad. His partnership with the Mexican government in this and in subsidiary companies was ended in 1918 by Carranza. To prevent control by American oil interests Díaz granted favored concessions to Cowdray, who had already obtained options on oil lands. Cowdray asked the Standard Oil interests to amalgamate with him. When they refused he started in 1909 his famous "oil war," in which the London and Washington governments were soon involved. Each side charged the other with bribery, arson and the theft of small holders' lands. By 1910 his company controlled 58 percent of the Mexican oil production. The fall of Díaz was, however, a serious blow to British interests, for the Madero government favored the Americans who had helped subsidize the revolt. Despite brief Standard-Cowdray truces in 1912 and 1913 Cowdray agents cooperated with Huerta, who overthrew Madero and rewarded Cowdray with concessions. From the time of Díaz' flight Cowdray had been negotiating for a sale to the Standard interests, but the British government, fearing American control, objected to the sale. After the United States entered the World War there was another oil truce, which ended with the Armistice. Finally, in 1919 Cowdray accepted a London government plan by which Royal Dutch Shell, the largest British combine, assumed management of his oil interests and continued in Mexico and elsewhere the Anglo-American struggle for international oil supremacy.

COXE, TENCH (1755-1824), American politician and economist. A Philadelphia merchant at the opening of the revolution, Coxé was at first a Loyalist, then a Whig, and after the conclusion

of the conflict he served as delegate to the Annapolis Convention in 1786 and to the Continental Congress in 1788. He believed thoroughly in the proposed constitution and allied himself with the Federalist party, holding the office of assistant secretary of the treasury from 1789 to 1792 and commissioner of the revenue from 1792 to 1798. Dismissed by Adams he turned Republican and was purveyor of public supplies under Jefferson from 1803 to 1812.

He was an ardent believer in the development of the merchant marine by navigation acts and of manufacturing by a protective tariff. He held that commerce and manufactures in a country would complement and invigorate agriculture, particularly in the case of a redundant staple such as cotton. He devoted much space to the exposition of these theories in such pamphlets as *An Essay on the Manufacturing Interest of the United States* (Philadelphia 1804) and *An Enquiry into the Principles on Which a Commercial System for the United States of America Should Be Founded* (Philadelphia 1789). Few if any of his contemporaries excelled him in his knowledge of American economic conditions, and his *A Brief Examination of Lord Sheffield's Observations on the Commerce of the United States of America* (Philadelphia 1791) and *A View of the United States of America* (Philadelphia 1794) are a mine of dependable source material for the economic historian. When the federal government made its first effort in the census of 1810 to collect information respecting manufactures, Tench Coxé was employed to compile the digest, *A Statement of the Arts and Manufactures of the United States of America for the Year 1810* (Philadelphia 1814), and his ability in organizing the somewhat inadequate data of the census collectors has given him a secure position among American statisticians.

CRAFTS. *See* INDUSTRIAL ARTS.

CRAIG, JOHN (first half of the nineteenth century), British economist. Very little is known about his life except that he was elected in 1818 to the Fellowship of the Royal Society of Edinburgh, from which he resigned about 1840.

Craig is the author of the *Elements of Political Science* (3 vols., London 1814) and of *Remarks on*

some Fundamental Doctrines in Political Economy (Edinburgh 1821). In the latter work he points out the futility of Smith's distinction between productive and unproductive labor, discloses the fallacy of Ricardo's doctrine of the inevitable opposition between profits and wages and dwells on the analogy between revenue from land and that from capital. He was the first writer in English to stress the connection between utility and value and came near to expressing the idea of marginal utility.

Craig also made some distinct contributions to public finance. He was the first Englishman to work out the equal sacrifice theory of taxation, drawing from it conclusions in favor of the principles of graduation and differentiation. He was also the first of the nineteenth century economists to emphasize the capitalization theory of taxation.

CRAMB, JOHN ADAM (1862-1913), British historian and political writer. He was born at Denny in Scotland and studied at Glasgow and Bonn universities. In 1893 he was appointed professor of modern history at Queen's College, London. His importance rests chiefly on his two books, *Reflections on the Origins and Destiny of Imperial Britain* (London 1900) and *Germany and England* (London 1914). Cramb was an intellectual product of the imperialistic nationalism that culminated in the Great War, but which in England was at its height in the last decade of the nineteenth century. It was perhaps his logical Scottish mind that made him carry his militarism to more uncompromising extremes than any other British thinker. "There is nothing in our annals," he proclaimed, "which warrants evil presage from the spread of militarism," and he characterized war as being "the supreme act in the life of the State." Accordingly, when it became evident to him that Germany was preparing for war against England, he positively welcomed the prospect and was only confirmed in his affectionate approbation of the rival power. Cramb sought to enlist the admiration of his countrymen for the most extreme manifestations of Prussian militarism. Even Bernhardt's ferocious outpourings seemed to him fair and just in their soldierlike simplicity.

Although he himself was full of esteem for the militaristic and imperialist ambitions of Germany, in which he saw the embodiment of the ancient Teutonic spirit, his works became the weapon of anti-German propaganda before and during the World War both in England and the United States.

ESMÉ WINGFIELD-STRATFORD

CRANE, WALTER (1845-1915), English artist. Crane began his career as an engraver and painter, but his greater fame came with the application of his talent for design to the crafts, including pottery, fabrics, plaster relief, mosaic, stained glass and especially book decoration. He believed that with the decline of handwork western industrial civilization had lost the basis of popular culture. Thus Crane and William Morris, inspired partly by Ruskin and Rossetti, led a movement to bring the arts and crafts into closer connection with one another and to give art a more substantial place in the things of everyday use. Finding that their work did not reach the public through the ordinary channels of commerce they founded in 1884 the Art Workers' Guild, with Crane as its first president; and in 1888 the first Arts and Crafts Exhibition in England was held. As a leader of the arts and crafts movement Crane's influence outside England eventually surpassed even that of Morris.

Crane was also one of the group, led by Morris, whose revolt against the ugliness of contemporary civilization led them into the Socialist party. Crane was an active worker for the cause, lecturing and contributing pamphlets and cartoons. He attacked capitalism because he believed that, while degrading the artist, it robbed the people of that liking for significant form and color which they show in all uncommercialized cultures.

CRANMER, THOMAS (1489-1556), first archbishop of the English Protestant church and leader of the English Reformation. According to

generally accepted evidence Cranmer in 1529, still almost unknown outside academic circles at Cambridge, suggested to Henry VIII the solution of the divorce problem and perhaps the outline of the Reformation itself as later executed. He became at once important at court, undertook embassies about the divorce to Germany and became archbishop in 1533. He promptly married Henry to Anne Boleyn, treating the marriage to Catherine as null and void; sponsored the new statutes and ecclesiastical expedients; later declared Henry divorced from Catherine; and convinced the clergy in general of the lawfulness of the Reformation, securing their almost unanimous support. An outstanding exponent of the prevailing doctrine of Erastianism, he championed the royal headship of the church as well as the reorganization and reduction of the power of ecclesiastical courts. His strong democratic sympathies, which revealed themselves in his opposition to the encroachments of the new nobility, prompted him also to sponsor the translation of the Bible into the common tongue and religious services into a vernacular intelligible to the common ear. Although he had little to do with the dissolution of the monasteries his opposition to the Act of the Six Articles and the attainder of Cromwell nearly cost him his influence and life and forced him to temporize until the accession of Edward VI. He then secured the adoption of his full plans, his *Homilies* (1547), his *Catechism* (1548), his *Book of Common Prayer* (1549) in English, the marriage of the clergy and communion in both kinds. But the second prayer book of Edward VI (1552) and the Forty-Two Articles (1553), in which doctrine was first restated, were his greatest achievements. With some omissions and changes they became the present prayer book and the present Thirty-Nine Articles, the influence of which upon English language, English style, education and life have been incalculable. He was the true founder of the Low church, its doctrines and practices. Because of his fear that the heterogeneity of Protestant doctrine throughout Europe might cripple the Reformation movement he attempted, although unsuccessfully, to arrange in London a Protestant council, to be attended by leaders of all the continental sects with a view to preparing a conciliatory body of doctrine on which might be built a united Protestant church. Therefore Cranmer's doctrinal reforms, although they directly affected only the English church, cannot be fully understood except in the light of this

broader purpose. His rigorous opposition to Rome has somewhat overshadowed the very important part which he played in keeping the English church free from Zwinglian domination. On the accession of Mary he was deprived of all his offices, tried for treason and then for heresy and suffered martyrdom in 1556.

CRAWLEY, ALFRED ERNEST' (1869-1924), English social anthropologist. Crawley was an exceptionally brilliant and many sided man, a classical scholar, headmaster and a sportsman as well as an anthropologist. All his works are distinguished by great originality of outlook, and his anthropological writings are also notable for their literary qualities and for their almost Frazerian volume and weight of reference to authorities.

Crawley laid the foundations for the scientific treatment of primitive sexual and social relations. At a time when Westermarck's exclusively biological treatment of savage sexual relations and the exclusively legal standpoint of such writers as McLennan and Maine held the field, Crawley opened wider vistas by the use of a profound psychological analysis on the basis of biological common sense. His main thesis was the attribution of marriage and all the social relations connected with it to a fundamental antagonism between the sexes, an antagonism which he ascribed to the processes of "physiological thought," whereby savage man was led to fear contact, and especially sexual contact, with woman because of the contagious qualities of her weakness and general inferiority. To this antagonism and fear Crawley traced the sexual and commensal tabus and avoidances. Marriage and its subsidiary ceremonies—betrothal, defloration, sexual resistance—he regarded as rites of union (or, by anticipation, as *rites de passage*) intended to lessen and to combat the dangers feared from contact.

Crawley's detailed extension and application

of this view displayed remarkable prevision of the course anthropological theory has since taken. He anticipated, in particular, functional anthropology by considering "survivals" not as fossil forms in a living culture but as ideas which spring from permanent functional causes. As pointed out by Freud, Crawley expressed certain of his views in terms that are hardly distinguishable from those employed by psychoanalysis.

CRÈCHE. See DAY NURSERY.

CREDIT. Etymologically the word credit means belief or trust; in its technical usage it has come to be confined to the trust placed in a debtor. Credit, in fact, is best understood as simply another name for debt. The two parties to a debt are called debtor and creditor, and the same relation which from the debtor's standpoint is called a debt is called from the creditor's standpoint a credit.

Debts play a fundamental part in economic relations. Every purchase and sale of goods or of services creates a debt due from buyer to seller. The quotation of a price is an offer acceptance of which gives rise to a debt. It likewise gives rise to an obligation on the part of the seller to deliver the goods or to render the services stipulated, but this type of obligation is not a debt. A debt is a pecuniary obligation; it is expressed as a number in terms of a unit which is called a "money of account." The debt may be discharged immediately by the buyer's delivery of the agreed price in money or it may be left outstanding, to be discharged at a future time. It becomes necessary then to keep an account; hence the expression money of account for the unit in which debts are reckoned.

Debts do not arise only out of purchase and sale of goods and services, but also out of borrowing and lending of money or of pecuniary rights. The borrowing and lending (or hiring) of goods with an obligation to return the same goods are not credit transactions. The obligation connected with it is not a pecuniary obligation and therefore is not a debt. If the

goods are not returned, the owner may recover pecuniary damages, and as soon as his right is established a debt is created, but that is not a part of the original transaction. Likewise, if anyone is entrusted with goods for safe-keeping he is not a debtor, because his obligation is not a pecuniary one. Even if the goods entrusted to him be money, with the stipulation that he is not merely to return an equal sum of money but to keep and return the identical pieces deposited, that is not a credit transaction. If he were simply a debtor, he would be free to pay the sum due in any form of legal tender he chose, and in the interval could part with the pieces of money he had received.

Debts are legally payable in money. It is essential to have some means established by law for the definitive extinction of a debt, for otherwise a court of law would be unable to prescribe a settlement, and the obligation of debtor to creditor would not be enforceable by law at all. Money is so established by law, and every piece of money is given a value or debt paying capacity in terms of the money of account. Thus the ideas of debt and money of account are more fundamental than that of money in the sense of legal tender currency. Debts cannot be defined in terms of money because money must be defined in terms of debts. But once money is established by law, every debt or pecuniary obligation becomes thereby an obligation to pay money.

In practise, however, it is not always necessary for debts to be discharged in money, which is a convenient medium for small payments but offers considerable trouble and cost in handling, safe keeping and counting when used for large payments. The possible alternative is payment in credit. A debt can be extinguished by being set off against another debt. Two traders doing business together can keep a running account in which the debts and credits of each are recorded, and only the net balance due from one to the other need be paid from time to time. But this method cannot in general be carried very far, because a trader's debtors are not usually the same people as his creditors. If, however, a group of traders made a practise of transferring all their credits to one individual, that individual would be able to set off the debts and credits of every trader and to claim the debit balance due from some so as to make good the credit balance due to the others.

One of the principal functions discharged by

a banking system is to make possible that the debts and credits of the customers of the system be set off or cleared against one another. A customer by assigning his credits to his banker makes the banker his debtor for the amount, and is then in a position to pay his debts by assigning to his creditor sums thus due to him from the banker. Debts due from bankers to their customers and destined to be used in this way are called bank credit.

The use of bank credit as a means of payment requires that some ready method should exist for assigning a debt from one creditor to another. The assignment of debts accordingly assumes a fundamental importance in the history and in the theory of credit. In mediaeval Venice, if anyone wanted to transfer to another a sum held to his credit at a bank, the two would attend in person at the bank and the substitution of the new creditor for the old in the books of the bank would be recorded before witnesses. In the Middle Ages legal recognition was already being given to a less cumbrous method of transfer by documents, called in modern usage credit instruments. If the terms on which a debt was created provided that it could be transferred from one creditor to another without the intervention of the debtor, then this simplified procedure became permissible.

Perhaps the most obvious method of assigning a debt is to embody it in a promissory note, a written promise to pay a specified sum of money, without limiting the promise to any specified creditor. The promise may be simply to pay the bearer of the note whoever he may be, and the debt can be assigned from one creditor to another by simple delivery from hand to hand. Or the name of a creditor may be specified, but accompanied by the alternative of payment to anyone else whom he may designate or order. The creditor specified may then assign the debt to a new creditor or payee by writing and signing on the note a direction to pay to the latter; this is called endorsing the note, because the direction is customarily written on the back of the note. If the creditor simply endorses the note with his signature without naming any new creditor or payee, the note becomes payable to bearer. Promissory notes payable to bearer on demand have acquired a special importance in the form of banknotes. Promissory notes payable to order and transferable by endorsement are extensively used in the United States as instruments of

short term borrowing and lending. In most other countries this function has devolved on the bill of exchange.

A bill of exchange is a written order by the creditor (the seller of goods) to the debtor (the buyer) to pay the sum due to the bearer or to a specified person or order. It is thus a more direct means of assigning a debt than a promissory note, since it is originated (drawn) by the creditor instead of by the debtor. If the buyer and seller of goods agree that the latter is to pay not immediately but only after an interval of time, a bill of exchange will be the means of assigning a debt due after that interval. Usage requires in that case that the buyer should recognize the debt by accepting the bill, i.e. writing his signature on the face of it.

In order that full advantage may be taken of the system of bills of exchange, there is required a class of people to act as intermediaries to present the bills to the debtors for acceptance and payment. This function ordinarily devolves upon the bankers. The seller of goods draws a bill on the buyer and makes it payable to his own banker. The banker may himself have an establishment in the place where the buyer is, or he will be in correspondence with some other bank there. He will transmit the bill there to be accepted and paid on maturity (collected). If he has confidence in his customer (the seller), the banker will be willing to discount the bill, i.e. to advance immediately to the customer the value of the bill, less interest calculated for the interval up to maturity (discount). If he does so, he is buying the debt represented by the bill and in effect lending the amount to the customer, but the customer is assumed in law to guarantee the bill in his capacity as drawer.

Whether he discounts the bill or collects it on maturity, the banker is carrying out an "exchange" operation, i.e. exchanging a credit or pecuniary right in one place for one in another; if the bill is drawn on a place in a foreign country it is a foreign exchange operation. Bills of exchange enable debts in different places to be cleared through the banks dealing in the foreign exchange market.

One particular form of bill of exchange, the check, has come into use in modern times as the predominant method of assigning bank credit in large sums. The check is a bill drawn on a banker by a customer and payable on demand. Being payable on demand, it is a means not of borrowing and lending but only of

payment. The possessor of bank credit draws checks upon the bank in favor of those to whom he has to make payments; the payees, who in all likelihood also have banking accounts, pass on the checks (endorsed, if payable to order) to their banks. Thus any bank receives checks drawn upon other banks, and it is usual for the banks carrying on business at any center to settle accounts with one another by sending the checks they receive to a central clearing house, where their respective debits and credits are calculated day by day, and net balances are paid either in money or by checks upon a central bank. Checks are used both for payments between people in the same locality and for payments at a distance. For payments between different countries they are first dealt in by the foreign exchange market and then passed on to the place on which they are drawn to be cleared. Thus credit instruments may be divided into two classes: first, promissory notes and bills of exchange, which promise or direct payment at a future date and which are therefore used as vehicles of borrowing; and second, checks and banknotes, which are used as vehicles of payment.

Payment by check or banknote is payment in credit, because it is effected by the transfer of bank credit. It should be mentioned, however, that banknotes, particularly those issued by central banks, are often made legal tender, and are thereby technically constituted money. The distinction between credit and money then becomes obscured. If the note is not legal tender in payments by the bank which issues it, but only in payments by others, it still may be regarded as credit, for it still represents a debt due from the bank. But if it is legal tender in payments by the issuing bank, that bank when asked to pay one note can do so by handing over another, and there is in substance no enforceable obligation at all. This is so even when the bank is obliged to convert its note into gold bullion. For bullion as distinct from coin is not money but a commodity; the delivery of gold bullion is not a payment but a sale; and the obligation, not being pecuniary, is not a debt. In some cases the legal tender notes of central banks are not given the form of credit instruments or promissory notes, but simply show the amount for which they are to pass in payment.

Credit instruments commonly possess the characteristic of being negotiable. In general if anyone assigns his property rights in an

object to someone else, he cannot give the recipient a better title than he possesses. If he is selling goods which he has stolen or misappropriated, the purchaser may have to give them up (unless he has bought them in "market overt"). But these rules do not apply to money. When a thief pays stolen money to an innocent person, the latter acquires a perfectly secure title to the money. A negotiable instrument is a credit instrument which in this respect has been put on the same footing as money. The law allows a clear title to any honest recipient, and he is under no obligation to inquire whether the previous holder had a clear title. This privilege belongs to both bills and notes, whether payable to bearer or to order, although they can be divested of it by writing the words "not negotiable" upon them. The effect of negotiability is to facilitate the use of credit instruments as substitutes for money, i.e. as means of payment.

Bank credit is composed of simple debts due from banks. Money is not entrusted to a bank by its depositors in the same way as valuables may be entrusted to a bank for safe keeping, or as money may be placed with a banker on the understanding that he is to act as a trustee. When a customer simply pays in money or checks to his account with the banker, the banker becomes a mere debtor for the amount, and assumes no other obligation to the customer than the agreed terms of the debt. The customer has no say in the use the banker chooses to make of the resources he thus acquires.

Bank credit includes certain other forms besides deposits which can be drawn on by check payable on demand. There are time deposits, employed by the depositors as temporary interest earning investments for idle funds. Again, there are credits granted by a bank which may only be drawn upon by bills of exchange of an agreed type, bank acceptances; they cannot be drawn upon by check or withdrawn by the customer in money. Such a credit is required by a customer who is a buyer of goods and who wishes to authorize the seller to draw a bill. If the bill is drawn on the bank instead of on the customer it will be discounted on favorable terms, because the bank will possess better credit than an individual trader. The document by which a bank authorizes a customer to open a credit is called a letter of credit. A similar term is applied to the document by which a bank enables a customer who is traveling to

draw checks upon its branches and correspondent banks.

A bank has a dual function: in its capacity as debtor it supplies its creditors with the means of payment in the form either of banknotes or of checking deposits; in its capacity as creditor it is a short term lender to traders and others. Short term lending by a bank is effected partly through the discounting of credit instruments (bills and notes), and partly through advances (loans and overdrafts), which are simple book debts recorded in the books of the bank against its customers.

When a bank lends to a customer, it creates credit. Two debts come into being: a debt from the customer to the bank payable at an agreed future date, and a debt from the bank to the customer due immediately and available as a means of payment. Like all debts, such debts are payable, if the creditor so desires, in money. In view of the superior convenience of money as a medium for certain kinds of payment (wages, small retail purchases, railway fares, etc.) every bank must be prepared to pay its obligations in money so far as its customers may require. This condition limits the freedom of banks to create credit as a means of payment, because if they are too lavish they may run short of money. Credit has thus become very intimately linked up with monetary policy. A system of central banking has been evolved under which the banks in any country all rely on a single central bank to supply them with whatever money they may require. The use of metallic coin in circulation, except subsidiary token coin, has been almost entirely superseded by paper currency in which the notes of the central bank play a predominant and in some countries an exclusive part.

Short term lending is performed mainly by banks, but not quite exclusively so. In London there is a highly organized discount market, in which bills are bought and sold by discount houses or bill brokers, to whom the banks lend money at call. The discount houses are accustomed when necessary to borrow from the Bank of England or to rediscount bills, and loans to the discount houses are regarded by the lenders as a highly liquid asset. There are other lenders besides banks, who take advantage of the discount market to gain a higher rate of interest than the time deposit rate allowed by banks on large funds temporarily available. In New York there is a market in call loans to stockbrokers which has something of the same impersonal

character, in that loans are regularly made by banks at competitive rates to others than their customers or by business corporations investing temporary surpluses. The call market grew up before the Federal Reserve system was instituted, and the rediscounting facilities now available have made it somewhat less important. Market dealings also exist in the United States for commercial paper (promissory notes) and for bank acceptances.

Side by side with the credit which is organized through banks and quasi-banking institutions or mobilized through credit instruments, there survives the more elementary form of book credit between buyer and seller. It is used not only in dealings between manufacturers, wholesalers and retailers; book credits are created also in sales to final consumers in the form of charge accounts and obligations payable on instalment. Finally, it is not to be overlooked that speculation gives rise to a form of book credit. Thus when a speculator buys commodities, securities or foreign exchange for delivery at future dates he incurs a debt equal to the price for the period of the transaction.

If credit is merely another name for debt, it is equally applicable to the long term debts which play a prominent part in the investment markets of the world. Governments, municipalities, corporations and individuals are accustomed to contract debts involving the payment of capital sums at the end of a considerable period of years, and the payment of interest meanwhile. Such debts are sometimes dealt in through the medium of bonds, payable to bearer or transferable by endorsement, which are credit instruments on the same footing as bills and notes, and the interest is paid by means of coupons or warrants, which are attached to the bond and are cut off when due and presented for payment like checks. Alternatively the rights of the creditors may be recorded or registered in books of account in which any change of ownership has to be entered in order to be effective.

An essential condition of the extensive use of credit is the existence of suitable facilities, practical and legal, for the provision of security for debts. There may be default on a debt either through the fraud or negligence of the debtor, or through the failure of the debtor's assets. To guard against that contingency, the creditor may as a condition of the loan require the debtor to assign him legal rights over some specified asset of sufficient value to cover the

amount of the debt with a margin for the risk of depreciation. If it is possible for him also to take physical possession of the asset, that is an additional safeguard.

When a bank lends to a trader, the borrower usually intends to acquire some marketable goods or securities with the sum lent. If goods in transit are financed by a bill of exchange, it is possible to secure the bill upon the goods by attaching the bill of lading to the bill, so that the holder of the bill is the holder of the title to the goods. But the bill of lading has to be detached when the owner of the goods wishes to sell them, and accordingly this form of security is not usually made use of, except in the interval before the bill of exchange is accepted. The bill, once accepted, becomes the recognized debt of the acceptor, guaranteed by the drawer and also by any intermediate holder who has endorsed it. If some of these parties to the bill are people of unimpeachable credit, collateral security ceases to be necessary. Sometimes notes or bank advances are secured by a lien on goods in warehouse or even in course of production (e.g. growing crops). Sometimes they are secured by bonds, stocks or shares which can be deposited with the lending bank or transferred to it.

The bonds or debentures of a corporation will be secured on the assets of the company. Either a corporation or an individual may provide security by a mortgage on land, buildings or other real property. The creditors of a government usually have to depend on its good faith, but sometimes they endeavor to reinforce their security by getting some government property or source of revenue assigned for the purpose and placed under independent control.

Security is not invariably required for debts. The creditors of a bank are usually content to leave their deposits unsecured. Banks often grant advances or overdrafts without security to customers of unquestioned solidity and probity.

Credit is essential to the economic development attained in the modern world. If we imagine a community without the practise of borrowing and lending, we must suppose every trader to be limited in the scope of his operations by the need to provide cash for all purchases. He must so conduct his business that the maximum need of working capital will not exhaust his resources, and the result will be that, when the need of working capital is at the minimum, he will be encumbered with a

large balance of idle money. If he ties up too much of his capital in permanent investment in his business, he may miss lucrative trading opportunities for want of ready cash, or may even be involved in serious embarrassment through unforeseen losses. If on the other hand he keeps a large cash balance, the scale of his normal business is unnecessarily restricted so long as the opportunity of employing the cash does not arise. In the complete absence of credit institutions, every trader's position would be a compromise between these two disadvantages. All capital invested would be irretrievably sunk, and the amount of liquid resources available to cooperate in any important new development would be extremely limited.

It would seem that even in a community without credit institutions joint stock enterprise would still be possible, since a shareholder is not a creditor but a participator. In fact, however, joint stock enterprise could not easily assemble large capital sums without the assistance of credit. It is not usually possible to interest more than a very limited circle of people in a new enterprise, and if capital could only be collected from actual cash balances the amount that they could spare would probably be very small. Credit institutions enable the participators to pledge their existing resources even though these are sunk in fixed capital; moreover, the participators can supplement the capital so raised by pledging the growing assets of the new enterprise. They might, it is true, sell their existing capital assets instead of borrowing upon them; but the market for capital assets could itself hardly exist without credit institutions.

The free functioning of a market requires an adequate concentration of liquid resources in the hands of dealers. The daily turnover of the markets must be large in comparison with the greatest single transaction it is called upon to carry through. If there are a hundred dealers in a market with available liquid resources averaging \$100,000 each, then without credit facilities the market could buy and hold \$10,000,000 worth of the goods dealt in and no more. Once the limit is reached, buying would come to a dead stop. If on the other hand a dealer can borrow \$9000 on the security of \$10,000 worth of goods, the limit is thereby raised tenfold to \$100,000,000 worth. And if dealers, in addition to the capital which they place directly in the market also have other investments, they may increase their dealings

still further by pledging these investments. If, as is usually the case, the dealers as a body do not extend their transactions to anything like the extreme limit of their credit, every offer for sale will find buyers with extensive reserves of purchasing power; the market functions smoothly and quotes a definite price for the goods dealt in.

In the particular case of financial markets, where the dealings are in stocks and shares, foreign exchange or insurance, dealers must be prepared to buy and sell very large units. Even with the most highly organized credit system, it is only possible to establish effective markets of this kind at a very limited number of great centers throughout the world. Without credit facilities there could be no markets, in the strict sense, at all, and every transaction would be the subject of intricate non-competitive bargaining. It is only in virtue of the existence of adequately organized financial markets that enterprise on any great scale is possible, and credit institutions are an indispensable condition of the whole system.

Credit supplies the modern world with its principal medium of payment. Thereby are secured an economy in the use of the precious metals, a saving of the labor and cost which would otherwise be involved in handling, counting and safe keeping specie, and, more important still, the vital advantage of elasticity in the monetary system. It is true that elasticity lends itself to abuses. Thus one of the essential features of the business cycle, with its undesirable recurrences of trade depression, is a credit cycle, an alternation of credit expansion and credit contraction, manifesting itself in periods first of rising and then of falling prices. But it must not be assumed that an alternation of prosperity and depression would not exist in a community on a purely specie system without credit institutions. On the contrary, the elasticity conferred on the monetary system by credit affords the best hope of avoiding monetary fluctuations by scientific regulation of the currency.

CRÉDIT AGRICOLE MUTUEL. See CO-OPERATION, section on FRANCE.

CREDIT CONTROL is a term of very recent origin which has come into general use only since the World War in connection with proposals emanating from many different quarters for monetary management, monetary stabilization and similar reforms. It is employed somewhat vaguely, but the general notion underlying all the uses of the term is one in contradistinction to the "automatic" devices for the regulation of credit which were supposed to characterize the working of the pre-war gold standard in its purest form.

Under an "automatic" or "unmanaged" system the quantity of reserve money available for a country's banking system in the shape of legal tender money and deposits at the central bank is determined, according to some more or less rigid formula, by the movement of gold between that country and the rest of the world. Under such a system the authorities of the central bank need, theoretically, do nothing except allow the quantity of credit to be fixed by the movements of gold and the official discount rate to adjust itself to the market rate corresponding to this quantity of credit. The equilibrium of relative price and wage levels and of relative interest rates at home and abroad is thus left to find its own level as the final outcome of the consequences of the fluctuating scarcity or abundance of credit determined by the movements of gold. As contrasted with these methods of laissez faire credit control is used to describe a system in which the central banking authorities deliberately determine, sometimes in anticipation of gold movements and sometimes in disregard of them, both the quantity and the price of credit with a view to the achievement of certain economic objectives, such as price stability or stability of employment and output or stock exchange stability. Although it is admitted that a country under a gold standard cannot persist indefinitely in a policy which disregards gold movements, experience has shown that a financially strong

country or one with large gold reserves can ignore their effects for a considerable time.

This clear cut distinction between credit control and its opposite is, however, merely theoretical. In practise no country which has reached the stage of using representative money and bank credit can employ an automatic system of credit regulation; indeed, no banking system of the modern type, such as has existed for a century past in Great Britain, can avoid some amount of credit control. The contrast between the presence and the absence of credit control in the modern sense reduces itself therefore to a difference in methods and degree. The old fashioned system was wont to regulate deliberately the price of credit, that is, the bank rate or discount rate, but to allow the quantity of credit to be determined partly by the movements of gold and partly by the amount of rediscounting at the central bank attracted by the official rate. Moreover, the main objective of the old system was the maintenance of gold convertibility of the country's representative money at the parity fixed by law, and it was reluctant to admit any primary duty, obligation, responsibility or interest in any other matter. The new fashioned system of credit control, on the other hand, employs not merely bank rate policy but every other weapon in the armory of a central bank in order to regulate the quantity and price of credit. It resorts to open market operations, i.e. purchases and sales of assets, chiefly government securities, on its own initiative rather than that of its customers; moral pressure or disciplinary action directed toward member banks and investment houses, particularly those engaged in floating foreign issues; variation within narrow limits of the official buying and selling prices for gold; and operations in the foreign exchange market, including the use of "gold exchange management" methods. Furthermore, the modern exponent of credit control is apt to regard the maintenance of gold convertibility not as the final crown and consummation of a central banking policy but rather as a somewhat risky limiting condition. It comes to his notice chiefly as something liable to interfere with the attainment of that particular type of economic stability which he regards as the bank's primary objective.

Some critics of modern methods of credit control have maintained that in the end they come to the same thing as old fashioned bank rate policy, inasmuch as the quantity of credit

employed is uniquely determined by the rate charged for it, so that little or nothing is really gained by trying in addition to control directly the quantity of credit. It is, however, generally agreed that open market operations allow a more sensitive and delicate control of the monetary machine than is possible by the use of the bank rate alone, which cannot help working by discontinuous jerks. Moreover, such critics are prone to underestimate the independent efficacy of open market policy as a means of credit control.

The historical evolution of credit control has been briefly as follows. Bank rate policy as a method of control was evolved during the nineteenth century, mainly in London, where it originated in the discussions which followed the monetary crisis of 1836-37 and preceded the Bank Act of 1844. Before 1837 it is difficult to find any trace of such ideas—they are not to be found, for example, in the works of Ricardo—at which it is a sufficient explanation to remark that up to the repeal of the usury laws in 1837 the rate of interest was subject to a legal maximum of 5 percent. By 1844 typical reformers, such as Lord Overstone (*Thoughts on the Separation of the Departments of the Bank of England*, London 1844, republished in his *Tracts and Other Publications on Metallic and Paper Currency*, London 1858, p. 237-84), were emphasizing the importance of bank rate policy as a means of regulating the volume of the note circulation. In 1861 in Goschen's *Theory of Foreign Exchanges* (London) the effect of changes in the bank rate as a means of influencing the foreign exchanges was first expounded in a clear and definite manner. The subsequent evolution of ideas about the bank rate as a means of credit control into the form in which they were generally accepted before the war may be traced through Bagehot's *Lombard Street* (London 1873, ch. v), Giffen's "Gold Supply: the Rate of Discount and Prices" (*Essays in Finance, Second Series*, New York 1886, p. 37-88) and Marshall's evidence before the Gold and Silver Commission of 1877-78 (reprinted in his *Official Papers*, London 1926, p. 17-195). A systematic treatment of the theory of the bank rate is, however, difficult or impossible to find; one will search in vain the works of Marshall, Pigou, Taussig or Irving Fisher.

The creation of the Federal Reserve System in the United States in 1913 opened a new chapter in the evolution of credit control. This system was in certain essentials less like the

British system than perhaps some of its founders had believed it to be; and it soon became apparent that it would tend to develop on lines of its own. In the *First Annual Report* of the Federal Reserve Board (Washington 1915) there is already mention of open market operations, and central bank control of the volume of credit by the purchase and sale of assets on its own initiative has come to figure more prominently in the activity of the Federal Reserve banks than in the traditional British system. Open market operations in the United States have been employed as a regular policy on a large scale since the spring of 1922 and as a systematized policy under the authority of a central committee with definite objectives of credit control in view since April, 1923.

While the United States has been the scene of the most extensive application of the open market policy, a similar evolution has been proceeding in London. Even before the World War the Bank of England was known to employ this device, though at somewhat rare intervals, on a modest scale and for short periods; it sold consols for cash on the stock exchange and simultaneously repurchased them "for the account," which would be anything up to a month later, with the result that the basis of credit was correspondingly curtailed between the date of sale and the date of settlement of the repurchase. Today, however, the Bank of England employs open market operations, usually the sale or purchase of treasury bills, as a regular part of its machinery for the control of credit. Moreover, since the revision of the form of the Bank Return in November, 1928, the assets of the bank are shown in such a way as to render visible the extent of the variations due to open market operations: assets brought to the bank on the initiative of the market are entered as "Discounts and Advances" and assets purchased on the bank's own initiative as "Securities." A treasury bill will thus appear in one category or the other according to its origin.

A central bank, which is free to govern the volume of cash and reserve money in its monetary system by the joint use of bank rate policy and open market operations, is master of the situation and is in a position to control not merely the volume of credit but the rate of investment, the level of prices and in the long run the level of incomes, provided that the objectives it sets before itself are compatible with its legal obligations, such as those relating to the maintenance of gold convertibility or to

the parity of the foreign exchanges. This is subject, however, to certain further conditions discussed below.

Central bank control of the basis of credit in the shape of cash and reserve money operates on the economic system not directly but through its influence on the total volume of credit created by the member banks belonging to the monetary system. Credit control depends thus not merely on the control of the basis of credit but also on there being some more or less rigid relationship between the reserve resources of the member banks and the aggregate of credit which each of them is free to create. It is a vital feature of effective credit control by a central bank that it should lie within its power to determine directly or indirectly the total volume of credit created by the member banks.

Modern banking systems are divided into two groups, according as the relationship between reserve resources of commercial banks and their current liabilities is determined by law or by the pressure of custom or convention, the United States being the leading example of the first type and Great Britain of the second. Both the legal provisions which govern the situation in the United States and the conventional practices which rule in Great Britain are very rigid at any given time but have occasionally changed. It happens, however, that at present the legal provisions prevailing in the United States work out very nearly the same in practice as the conventions prevailing in Great Britain. In the United States a lower percentage of reserves is held against time deposits, but till money does not count as a part of the legal reserves; the net effects balance approximately the contrary practices in Great Britain. We may summarize them by taking the percentage of reserves held against the demand deposits as being between 10 and 11 percent in both countries. In some other countries there is a greater variability of practice. According to W. R. Burgess (p. 36) the typical ratios of reserves to deposits are as follows: four French credit companies 11.5 percent; Swiss private banks 8.0 percent; the chartered banks of Canada 11.0 percent. In Germany the reserve ratios are much lower and more variable, with the result that the Reichsbank's control over its member banks' credit policy is far less secure.

Whatever the objectives for the attainment of which the weapon of credit control is or

should be used, a central bank which adheres to an international gold standard must regard the maintenance of the gold value of its money as its primary objective; any secondary objectives which it may desire to pursue simultaneously must necessarily be limited in duration and in degree, except in so far as one bank is powerful enough or persuasive and influential enough for its behavior or its admonitions to influence the action of the other central banks belonging to the same international gold standard system. In an international system the attainment of objectives other than gold parity, such as the stability of prices, of incomes, of employment, or of stock market values, must largely depend not on the isolated behavior of a single central bank but on the average behavior of all the central banks of the system, each contributing its quota to the final result. Nevertheless, an individual central bank, which is in a position to absorb or part with a very large quantity of gold without being deflected from the pursuit of secondary objectives of its own, may in present circumstances profoundly influence the behavior of other central banks and even compel them to follow in its train.

Membership of an international monetary system involves certain obligations. A sound international system will be one which manages to combine a reasonable latitude to its constituent central banks to pursue local secondary objectives within defined limits with sincere collaboration between the constituent banks aimed at controlling their average behavior in such a way that those secondary objectives may be attained which are judged to be most advantageous to the world as a whole. Indeed, those objectives which are regarded as secondary from the point of view of any individual central bank adhering to an international gold standard can and should become primary objectives from the point of view of the *corpus* of central banks acting as a whole. The structure of credit control will therefore be finally completed only when individual central banks are ready to submit to a certain discipline from an international collectivity, analogous to the discipline to which their own member banks must be submitted if their local system is to work with a deliberate purpose.

CREDIT COOPERATION. Credit cooperatives are cooperative institutions of a banking nature which serve their members. In order to be classed as cooperative the associations must be voluntary, thus excluding compulsory co-partnerships; they must have as their aim mutual self-help with a view to some remote social goal of the participating social group, thus excluding commercial joint stock companies; and, finally, they must use as the method for attaining this end a type of procedure generally associated with the term business enterprise, thus excluding farmers' or peasants' unions, agricultural syndicates, trade unions or other forms of mutual interest associations. The legal form of organization is not always indicative of the cooperative character of these institutions. In most countries special legal forms advantageous for cooperatives and sanctioned by special legislation have been adopted, but the cooperative may assume the form of the ordinary joint stock company. Their distinction from other forms of cooperation lies in the fact that credit cooperatives perform banking functions, although they need not necessarily assume all the functions of an ordinary commercial bank. When the services of such societies are highly specialized, as in the cases of building and loan societies, burial funds and mutual insurance societies, the organizations are not considered credit cooperatives. Nor are central banking institutions of consumers' cooperatives to be confused with the credit cooperative; they are designed primarily to serve the banking needs of their constituent consumers' societies. The trade union banks, which in some instances may offer facilities to credit societies as well as to other cooperatives, also originate from different concepts and function in a different way. In the main, credit cooperatives are voluntary mutual aid associations whose functions are to provide credit on a personal basis to the middle class, both urban and rural, for the purpose of carrying on production and business and to workmen and salaried employees for consumption purposes. All of

these functions are often assumed by the same credit society.

The history of credit cooperation discloses great variations in time and place indicative of adaptations to special needs. Credit cooperatives differ in methods of capitalization, principles underlying the division of profits, administrative organization, the degree of centralization of the union or federation of societies and the setting up of a central cooperative banking institution. Considerable differences also exist on the broader questions of the relation of the credit cooperative to other forms of cooperative endeavor, to the church, to the state and to other social and political institutions. In a sense such differences may be interpreted as a reflection of the variation in character and orientation of democratic and reform movements in countries passing through different stages of capitalistic development. When due allowance is made for these variations, however, it is still possible to fix a number of basic characteristics of credit cooperation. For this purpose it is necessary to turn to a consideration of the earliest forms of credit cooperation as conceived in Germany.

The credit movement which developed under Hermann Schulze-Delitzsch's leadership can best be understood in the light of the economic and social development of Germany in the middle of the last century. The factory system in Germany was developed several decades later than in England or France, and unskilled factory labor had not as yet been sufficiently differentiated to justify a separate social grouping. The liberal leaders of the upper middle classes were profoundly interested in the fortune of the lower middle classes—the owners of small or medium sized agricultural enterprises, tradesmen, the humbler members of the various professions, the skilled craftsmen—whose economic position was just beginning to be undermined. Schulze-Delitzsch himself came from the small town of Delitzsch in Prussian Saxony which was typical of this economic and social grouping. He participated in the endeavor to aid these classes through philanthropic loan and provision societies, but his liberal democratic ideals convinced him that a firmer foundation on a co-operative self-governing and self-supporting basis must be laid. Although his plans included also consumers', home building and producers' cooperation, the eventual predominance of the credit union was assured, because the middle class membership which responded to his schemes was most in need of credit for produc-

tion purposes in manufacturing, trade and agriculture.

The credit cooperative as evolved by Schulze-Delitzsch is the fundamental groundwork on which all credit cooperation, both urban and rural, has been developed. Schulze-Delitzsch's plan provided for the inclusion of the rural element, and at least one quarter of the membership in his societies has at all times been agricultural. But in the southwestern part of Germany a rather different type of agricultural economy predominated. It was for the village community of that region, which included along with the peasant owners of small agricultural units a scattering of tradesmen, even a few factory workers and handicraftsmen, that F. W. Raiffeisen evolved that scheme of credit cooperation which has been adopted by countries and communities in a similar stage of rural development. The Raiffeisen movement included important and necessary adaptations of the Schulze-Delitzsch plan but there existed no basic contradictions in the two plans of development: both were based on the concept of mutual self-help operating through the medium of a business enterprise on such business principles as were compatible with the needs, training, traditions and capacities of the membership in whose behalf it was founded. Both movements despite some difference in degree of emphasis stressed in addition to sound business principles the idealistic aspects, which in Raiffeisen's case took on a deeply moral and religious although by no means sectarian character. Both were essentially middle class movements designed for the welfare of the less prosperous of that class and not for the rebuilding or replacement of the existing economic order.

The principles of German experience as developed by Schulze-Delitzsch, by Raiffeisen and later by Wilhelm Haas are fundamentally alike. The difference in methods arises out of special conditions. Schulze-Delitzsch appealed to a city group which had some financial resources and some commercial training. In order to found his banks on a sound basis and to attract capital he based membership on shares sufficiently low to appeal to most of the potential membership but sufficiently large to make the endeavor self-supporting. Both by principle and by policy Schulze-Delitzsch was strongly opposed to state aid. Where liability was unlimited, as it was at the outset in all Schulze-Delitzsch societies, each member could hold one share and one share only, thus retaining a cooperative demo-

eratic principle. In addition to share capital and the capital created through the liability of the membership, funds were secured through the savings and deposits of non-members as well as members, and the bank engaged in the discounting of bills of exchange. In order to attract this capital it was necessary to pay rates of interest approximating current commercial rates; in order to transact the business of the society, which covered a comparatively large territory and included many types of banking transactions, it was necessary to have a compact management and to engage an expert paid staff, which was supplemented, however, by a superior body drawn from the membership. Since the local banks engaged in commercial banking transactions, it was found most feasible for them, after experimenting with the establishment of their own central bank, to utilize a commercial bank, the Bank of Dresden, which created a cooperative department for this purpose. Loans were likely to be larger than in the rural unit, although perhaps not on such long terms. In the division of profits the principle of an indivisible reserve fund for the benefit of the enterprise was maintained, and usually about one fifth of the profit after the first year or two of operation went into this reserve fund. But the balance was distributed as dividends to the membership. While it was often true that not as large a percentage of the membership availed itself of the loans as in rural societies, nevertheless the provision limiting each member to one share, the provision requiring a reserve fund and the tendency to lower dividends on capital (as well as on loans) kept the society from turning into a profit making device for the shareholders.

Raiffeisen, on the other hand, began with an indigent population but slightly educated in business practice or principles. At the outset, in order to attract as large a membership of the poorer classes as possible, membership was not based on the owning of shares, but after the passage of a law requiring such shares a nominal share of about ten marks was created, payable in small instalments. Since the membership was for the most part land owning and the principle of unlimited liability was accepted, it furnished a basis for capital supplemented by the savings and deposits of members and non-members. Loans were made largely on the basis of character as well as of need, and in order to keep adequate supervision over transactions conducted on such a basis the credit society was kept small—within the confines of a parish—and

was given a moral basis and moral support, which Raiffeisen found in religion. For such a small unit the credit society could undertake other cooperative functions as well—marketing, purchasing and processing. Since the business transacted by such a small unit was comparatively simple, there was no necessity for a large paid expert staff; its most important decisions were made by a board of directors selected from the membership and functioning on an honorary basis. With shares at a purely nominal figure dividends were hardly feasible. All profits therefore were turned into an indivisible reserve fund, part of which was bound to be used for community improvement and for the development of other types of cooperative endeavor. Savings could be attracted at a lower rate of interest than in the city, and loans, which tended to be smaller than those of the urban credit society, were extended at a lower rate to members. The respect for centralized authority, characteristic of the small religious communities in which the Raiffeisen societies were built, and the variations in credit facilities made feasible the founding of a strong centralized federation and a centralized cooperative bank. Although Raiffeisen stressed as strongly as did Schulze-Delitzsch the element of self-aid, his views on state aid were by no means as pronounced. This factor and the support which the governments of the states extended to rural cooperatives led to the establishment by Prussia of a state bank which extended loans to cooperative societies at a low rate of interest.

The movement spread in the sixties and was adopted in either form or with variations by other communities and other countries. In practically all the countries of its adoption, as in Germany, there was no fundamental rivalry or separation after the first period of experimentation between the rural and the urban credit societies and the general cooperative movement. In some instances the urban credit society established rural branches. Only in Switzerland and Belgium are the city "popular banks" completely separate from the cooperative movement. Almost everywhere, as in Germany, the movement received its first impulse from members of the liberal bourgeoisie, such as Luzzatti and Wollemborg in Italy, Rostand in France and d'Andrimont in Belgium, who were interested in social reform, preferably without state aid, although usually advocating public supervision through auditing functionaries comparable with those provided for commercial banks. In some

countries, however, the movement to establish cooperatives has come from the state and with state aid, as in Japan, the Balkans and for some types of rural societies in pre-war Austria-Hungary; such action has been justified as necessary for the upbuilding of economically backward rural communities in these countries. In India, however, where the government has merely supervised and directed through public officials, the movement has gained greater strength through the absence of state financial aid. In France the attempt to create cooperative credit through the establishment of a state co-operative banking institution failed, and independence of state aid has enabled the credit co-operative to maintain that political neutrality which it deems necessary. In present day Italy and Russia the connection between the credit cooperatives and the state is a peculiar one; in most cases the societies are in complete subservience to the state and in Russia they perform a somewhat different function from that of credit cooperatives elsewhere. Before the World War the credit cooperatives together with other types of cooperatives were looked upon by certain minority nationalistic groups in Austria-Hungary, particularly the Czechs and the Poles, as a weapon in the nationalistic struggle; and the credit movements although in fact based on the German schemes were usually named after the national champions or creators of the movement. On the whole, credit cooperatives have also been neutral in religious matters, for Raiffeisen's emphasis on religious influence had no sectarian bias. But in countries where the general co-operative movement tends to be socialistic or where the rural element is profoundly bound to the Catholic church, separate Catholic movements, including credit cooperation as an important division, have sprung up—as in Italy under the direction of Cerutti, in Belgium under the leadership of Abbé Mellaerts and in the Netherlands. Within the movement itself there are the same variations in every country as in Germany regarding share capital, centralization, provision of a central banking system and similar problems of organization. Generally credit co-operatives adopt limited liability for their membership, although at the outset the German movement stressed unlimited liability.

The form which became established in most countries was the rural co-operative. Outside of Germany, the former Austria-Hungary, Switzerland, Italy and the Balkans the city credit co-operatives have been little developed as a means

of furnishing credit for production as well as consumption needs. In such countries as England and the United States, where the building and loan societies are widespread, the credit furnished by credit cooperatives is for consumption needs. In the United States the societies are often based on occupational similarity in contrast to the practise of mingling groups and occupations in most countries. Similar credit cooperatives for consumption needs have had a considerable vogue among salaried employees of both public and private organizations in the former Austria-Hungary and in Germany. The failure of the city credit co-operative to find foothold in as many countries as rural cooperation has can be explained by the fact that in most countries with a high degree of urbanization a definite factory class has emerged whose immediate consumption needs are better furnished by consumers' cooperatives, while the small manufacturers and tradesmen are either submerged by "big business" or make use of special facilities provided for them by the private banks.

The rural credit co-operative has been created mainly in those regions in which marketing, purchasing and producing cooperatives have not existed and in which peasant or small landowners have been at the mercy of usurers. In most of these countries, and especially where the credit society is confined to a small area, the credit co-operative has, as in Germany, undertaken supplementary cooperative functions. Particularly striking has been the transplantation of the system to such countries as the Philippines, Japan, India and the Dutch Indies. In the case of Japan the credit system was borrowed directly from Germany; in India this took place indirectly through the suggestions of Henry W. Wolff, who had studied German conditions thoroughly.

At the present time it is estimated that there are about 80,000 societies with a total membership of more than 25,000,000. Russia claims a membership of over 4,000,000 in its credit co-operatives. India has a membership of approximately 4,000,000 in societies predominantly credit in function. In Japan 12,400 societies, representing three fourths of the total number of all cooperatives, have credit functions and probably include over 3,000,000 members out of a total cooperative membership of 4,000,000. Because of the special nature of the Russian credit cooperatives the German credit societies still remain the most important on the European continent with a total membership of over

3,000,000. French credit societies claim a membership of over 400,000, Rumanian of over 700,000, Italy about 500,000. In order of importance there follow Czechoslovakia, Poland, Bulgaria, Yugoslavia and Greece, each with somewhat over 250,000 membership. Switzerland, Belgium and Austria do not lag far behind. The credit societies of the United States exclusive of building and loan associations include about 265,000 members. Other countries or regions with some development of credit co-operation are some of the Dutch Indies, Ceylon and Palestine. Almost 30,000 societies representing a membership of 9,000,000 are affiliated internationally with the International Cooperative Alliance, but owing to disputes in the early part of the twentieth century over the function of co-operation in the capitalistic system many of the powerful credit cooperatives, especially those of Germany, withdrew. Others, such as those of India and Japan, covering a large membership, have never been so affiliated.

In general credit cooperatives are a weapon for the middle class in its struggle for existence. In countries that are not highly capitalistic credit cooperatives are generally the first to create banking institutions, especially for personal credit and thrift. They replace the tradesmen and the usurers in supplying credit to the peasants and craftsmen; they introduce mutual aid and self-help in financial matters among the poorer classes, teach them to keep accounts and to budget and educate them to business responsibility. They eliminate competition for credit facilities and through operation on a co-operative basis reduce business profits by restoring earnings to the membership. In more advanced capitalistic countries they help the urban and the rural middle classes to maintain themselves against big business. They institute personal credit where none existed, they compete with existing banks and force them to show more consideration to small customers. Indeed, when well developed they also crowd out or at least hinder the growth of the smaller private banks by depriving these of their customers. It also often happens that well developed credit co-operatives change into profit banks. Naturally the credit cooperatives as savings depositaries also compete with municipal savings banks, post office savings departments and private banks. Although credit cooperatives are not always linked with government banks, credit co-operatives have in some instances paved the way for public banking by stimulating the organization

of government institutions to act as central banks for the credit societies and their provincial federations.

CREDIT FONCIER. *See* AGRICULTURAL CREDIT.

CREDIT INSURANCE is an outgrowth of attempts to meet the recurring business problem of losses from bad debts. With the definite emergence of factors who sold for account of their principals the necessity of making sure of payment by the customer led to the practise in England of paying a *del credere* commission in addition to the regular commission. For this extra commission the agent became surety for the payment of sums due to his principal from the customer, and such practise is embodied in present English law. Not only in cases where an agent is involved, however, but in any economy where the overwhelming majority of direct business transactions are made on a credit basis, confidence in the integrity of the debtor and his ability to pay is a prime necessity for business activity. The fact that annual losses in the United States due to fire are usually less than the annual bad account losses indicates the pressing nature of the problem. There is of course a certain normal percentage of loss which occurs regularly and predictably for various types of business and which must be regarded merely as an overhead cost. For these losses insurance is inadvisable, since the premium charged by an insurance company would have to be high enough to cover the anticipated almost certain loss plus all the expenses involved

in the collection of the premium and the settlement of the claim. But no normal calculations of a single firm can anticipate unusual losses such as those due to a general business depression or the insolvency of a very large individual buyer. It is the attempt to provide socially for this type of loss which has led to development of credit insurance, which provides indemnification to exporters, manufacturers, jobbers and wholesalers for unusual losses arising out of the extension of credit to their customers. Shipments to both domestic and foreign buyers may be covered by credit insurance, although domestic credit insurance developed independently and considerably earlier than foreign or export credit insurance.

A mutual company insuring against insolvency appeared in Paris as early as 1848 and an incorporated joint stock company in 1855, but their existence was brief and no stable successors appeared until 1923. In that year appeared the mutual insurance society *L'Assurance Française de Crédit*, writing both domestic and foreign insurance. In England and Germany the chief emphasis has been upon foreign credits, and it is in the United States with its vast internal market that domestic credit insurance has had its earliest and greatest development.

Although a successful insurance venture was launched in New Jersey as early as 1889, the real development of domestic credit insurance in the United States is inseparable from the growth of the American Credit Indemnity Company of New York, incorporated in 1893. This company, along with the London Guarantee and Accident Company, Ltd., and the Ocean Accident and Guarantee Corporation, Ltd., were the only underwriters in the field until 1916. Since that time several additional American companies have entered it. Domestic credit insurance has grown very slowly, however, and that it is not even now a major casualty line may be seen in the fact that the total premium income in the United States is only about \$5,000,000 annually. Restricted coverage, made necessary by lack of experience and difficulty in obtaining credit information, has limited its progress. Extreme variations in loss ratio, as for instance a loss ratio for the three principal companies doing business of 3 percent for 1919 as contrasted with 89 percent in 1921, create a serious problem of satisfactory premiums and reserves which will enable the insurer to retain clients during years of prosperity and be prepared to pay the heavy losses which occur in years of depression. Since

this risk is not controlled by physical causes it is inherently more difficult to estimate than most insurable items. Nevertheless, as the facilities for obtaining credit information have increased and the various companies have pooled their experience, more liberal policy terms have become available. Even so it is not yet possible to provide as full coverage as many firms desire and it may be that such perfection will never be obtained.

At the present time credit losses which are included under the policy are limited in several ways. In the first place, the event insured against is restricted to insolvency as defined in the policy. All policies contain at least twelve to fourteen such definitions, which are legal and technical in nature. Any one of them for example, the absconding of a debtor—makes the debt eligible for payment under the policy. In addition to these legal definitions other policies make the insurer liable if an account of a customer is past due and is filed with the insurance company for collection, sometimes within a specified period of time. Naturally the cost of the insurance is affected by the varying degrees of liberality of protection.

The only losses which may be considered to come within any definition of insolvency are those arising out of accounts which had an approved credit rating at the time the shipment of merchandise was made and usually for an amount not exceeding the maximum liability agreed upon in the policy for each of the several credit ratings. A table of ratings of customers' credit, usually based upon those of the more important mercantile agencies such as Dun's or Bradstreet's, serves as an approximate index of risk, and the typical policy fixes an individual account limit for each customer's account falling within a certain rating.

Every loss which qualifies under one or more definitions of insolvency and is within the scope of the table of ratings is subject to at least a 10 percent deduction, the percentage deduction being higher on the lower credit ratings. This practise is called co-insurance by the companies and is intended to make the insured a risk taker for a part of each extension of credit. Presumably this tends to eliminate the insurance of profits, or at least a part of the profits, and reduces the moral hazard.

The net amount of the compensable loss is still further qualified by deducting the normal loss from the amount of loss ascertained after the application of the preceding three limita-

tions. The normal loss, or the almost certain minimum credit loss which would in any case be sustained in any given year by the insured, is found by applying a certain percentage to the gross sales of the insured for the period covered by the policy (usually one year). This percentage is not uniform but varies with the total volume of sales and the type of business of the insured. There are about eight classes into which the insurable lines of endeavor have been grouped by the companies, depending upon the normal rate of loss which may be expected in those businesses. Among those lines listed as extrahazardous and not solicited are diamonds and jewelry, furs, scrap iron and junk, patent medicines and jobbing of woollens.

The determination of the premium is complicated and depends upon a number of factors. The more important of these are a charge for the number of thousands of dollars of protection obtained under the individual account limit specified in the table of ratings and a charge for the gross volume of sales. The amount of the charge for the individual account limit varies for the different ratings, and the rate per one thousand dollars of sales is lower if the sales exceed a certain amount.

In addition to serving as a means of indemnification of unusual losses this form of insurance serves as collateral on merchandise accounts financed by banks and as protection for accounts receivable as a business asset. It provides a conservative guide for the extension of credit and through collection service and its assistance in settling overdue accounts makes possible considerable salvaging on bad and doubtful accounts. It sometimes prevents loss when a concern is unable to pay its creditors at once because of inability to collect slow accounts; the insurance company can pay the creditors and wait for the slow accounts rather than allow a costly liquidation to be forced. It has been most frequently used in the following lines: lumber, iron, steel, coal, hardware, textiles, paper, advertising agencies, printing, shoe and clothing manufacture.

The idea of guaranteeing foreign debts goes back to the time of the South Sea bubble, and mutual pooling or sharing of credits has been practised spasmodically for over a century by merchants who found it necessary to combine their resources in order successfully to consummate some kind of commercial venture. The first foreign credit insurance policy is believed to have been written by one of Lloyd's under-

writers over thirty-five years ago and was confined to the insurance of commercial bills of exchange. In Germany prior to the war the credit problem in foreign trade was handled by the banks on the basis of information supplied by branch banks and the Schimmelpfeng Information Company. The banks served exporters by discounting without recourse, that is, cashing the bill drawn by an exporter with no further responsibility on his part even though the importer ultimately failed to pay. It is, however, only since the World War that foreign or export credit insurance has shown any great development. The post-war need for restoring confidence in foreign trade, handicapped by currency disorders and unprecedented political transformations, led to experiments in a number of countries. In 1919 Great Britain created an Export Credits Department maintained by the government to promote export trade, but in spite of many revisions and extensions of the original plan it has not been very successful. A private stock company known as the Trade Indemnity Company, Ltd., of London, established in 1917, has been since 1920 a most important factor in obtaining credit information on foreign buyers and guaranteeing the collection of accounts. During the same period the Frankfurter Allgemeine-Versicherungs-A.-G., founded in 1865, and the Hermes Kreditversicherungsbank, A.G., established in 1917, subsidized by the state and cooperating with the ministry of economics, have been the principal export credit insurers in Germany.

In France L'Assurance Française de Crédit, a mutual society founded in 1923, provides both foreign and domestic insurance, and La Nationale, Compagnie d'Assurances Crédit et de Réassurances de Toute Nature, established in 1924, furnishes reinsurance and credit insurance. L'Urbaine Crédit, organized in 1924, does an extensive business and reinsures with the Trade Indemnity Company of London. In Holland there is the Nederlandsche Crediet-verzekering Mij., established in 1925; in Italy the Società Anonima Italiana per l'Assicurazione del Credito Commerciale, established in 1927; and in Norway the Norsk Aktieselskap Promotor Kredit og Skadesforsikring, founded in 1924.

In the United States the American Manufacturers' Foreign Credit Insurance Exchange, formed in 1921, has been the only underwriting company of importance and all of the development in this country has been through private capital. In sharp contrast is the European situa-

tion, where the governments have usually reinsured the catastrophe hazard and frequently a part of the normal risk. Italy in 1927 organized a national institute of insurance to guarantee for the account of the state certain credits subject to special risks. In Germany the budget of 1926 contained a substantial sum for export insurance to be added to the sum provided for exporters dealing with Soviet Russia. In France the minister of commerce was authorized in 1928 to guarantee in the name of the state up to 60 per cent of the value of certain exports of national interest. Most of the private companies in European countries are of the stock variety, whereas the American Manufacturers' Foreign Credit Insurance Exchange is a reciprocal mutual which has combined a credit information clearing house with a system of guaranteeing the collection of foreign accounts. The reciprocal form of organization was selected for a definite purpose. It provides the best means for obtaining accurate data relative to the financial status of foreign buyers. No independent bureaux had been able to provide such information satisfactorily; but it has been possible to persuade firms enrolled as members of an insurance organization to supply information regarding their credit experience for mutual benefit at lowest cost of insurance.

In addition to the difficulty of obtaining credit information the guaranteeing of the accounts of foreign buyers is much more complicated than that pertaining to domestic buyers. The trade practises of the different countries vary, the fluctuating rates of foreign exchange affect the value of a bill of exchange, the laws with reference to insolvency are not uniform, and political considerations are frequently of importance.

Because of these hazards forms of policies for individual shipments only have been used extensively, and only a fraction, such as one half or three fourths of the bill of exchange, is insured. Floating policies covering all open accounts of buyers falling within certain territorial and credit restrictions are written now, however, and doubtless will become more liberal as the knowledge of this field increases. The premiums vary with the country in which the buyer is located, the terms of payment and the standing of the exporter himself.

Relatively the growth of export credit insurance has been more rapid than that of domestic credit insurance; and if the governments of the various exporting nations are willing to

reinsure the catastrophe hazard, undoubtedly this form of insurance will grow and continue to be of special importance in connection with the search for new markets.

CREIGHTON, MANDELL (1843-1901), English historian and churchman. Creighton was born of a merchant family in Carlisle. He studied at Oxford, entered the ministry and was bishop of Peterborough from 1891 to 1897 and of the See of London from 1897 until his death. He was actively interested in problems of education and was a member of the commission which drew up the statutes of the University of London. Creighton was likewise a potent force in the stimulation of historical studies, especially in ecclesiastical history. He became the first professor of ecclesiastical history at Cambridge in 1884, the first president of the Church Historical Society in 1894 and the first editor of the *English Historical Review* in 1886.

As a historian Creighton's chief importance rests on his *History of the Papacy from the Great Schism to the Sack of Rome* (5 vols., London 1882-94; new ed., 6 vols., 1897). He originally planned this work as a history of the papacy during the Reformation but found it necessary to go back to the weakening of papal power and prestige at the time of the schism. The Reformation was for him the most important event in

modern times. It was, however, not an inevitable outcome of the growth of Protestant evangelical spirit but rather a revolt against the absolutist administration of the papacy that could easily have been avoided by a more tactful and moderate policy of the popes. His work was intended not as a history of the Reformation but rather as an account of the papacy as a factor in European affairs.

Creighton's interest on the whole was more political than religious or social. Hence his complete neglect of the deeper religious forces at work and of the more important social aspects of the Reformation. The force of individual personality too was for him the most important factor in historical development. His history is thus a history of the popes rather than of the papacy as an institution, hence his characteristic method of concluding a period with a brilliant characterization of the leading personality of the time. In contrast to Lord Acton, whose historical writing was motivated and colored by a moral earnestness and passion for modern liberalism and tolerance, Creighton pursued what he called the historical method of progress. He aimed to "understand the past as a whole, to note in every age the thing that was accomplished, the ideas which clothed themselves with power" and above all to estimate these only in reference to the times in which they occurred. It is this which accounts for the moderateness of his treatment of the moral delinquencies of the Renaissance popes, a fact which brought down upon him the attack of Lord Acton. It is this also, perhaps, which accounts for the criticism of his work as dull and lacking in picturesqueness. "I am afraid," he once said, "that I regard history as a branch of science, not of novel writing."

CRÉMER, SIR WILLIAM RANDAL (1828-1908), British labor leader and peace worker. He was a worker in the building trades. In the period of reviving working class activity beginning in the late fifties and the sixties he was active in organizing unions, promoting industrial arbitration and championing democratic reforms. Out of the Workmen's Peace Association, which he founded in 1871, grew the International Arbitration League. This organization

sponsored propaganda, especially among workers, for the negotiation of general arbitration treaties and for the establishment of a permanent international court. Crémier was a working class member of Parliament from 1885 to 1895 and from 1900 to 1908 and was affiliated with the Liberal party, stoutly opposing the independent labor movement. In Parliament he opposed the increase of armaments, imperialism and the Boer War. In 1887 and 1895 he presented to the American government memorials bearing an impressive number of signatures of members of Parliament, urging a general arbitration treaty. An indirect result of the first memorial was the founding of the Inter-Parliamentary Union in 1889, in which he took the initiative. He played a prominent role in its subsequent development. His cooperation with French parliamentarians and labor leaders helped establish the *entente cordiale*. In 1903 he received the Nobel Peace Prize. Crémier's significance is twofold: he was one of the most important leaders in founding a realistic international peace organization and he effected a liaison between the labor and peace movements.

MERLE E. CURTI

Consult: Evans, Howard, *Sir Randal Crémier, His Life and Work* (London 1909); Davis, Hayne, *Among the World's Peacemakers* (New York 1907); Eickhoff, R., "Die interparlamentarische Union (1884-1914)" in *Zeitschrift für Politik*, vol. viii (1915) 452-93.

CRÉMIEUX, ADOLPHE ISAAC MOISE (1796-1880), Franco-Jewish statesman. Crémieux was the son of a merchant who was a town official in Nîmes during the Terror. He entered public life under the Restoration as defense counsel in a series of celebrated political trials. As deputy from 1842 to 1848 he sat with the dynastic opposition and after vain eleventh hour efforts to maintain the July monarchy joined the revolutionary government of 1848, serving as a link between conservative bourgeois and Left elements. Although he helped actively to quell proletarian risings he finally resigned because of his colleagues' increasing counter-revolutionarism. After supporting Louis Napoleon for president he joined the opposition and was imprisoned by the coup d'état. Released, he retired to the bar. He reentered politics as a republican in 1869, was minister of justice in the government of national defense in 1870-71 and in 1875 became a senator for life.

An ardent advocate of political emancipation for Jews, Crémieux refused to take the Jewish

outh (which was subsequently abolished), demanded equal government subventions for all cults, repeatedly proposed diplomatic action on behalf of French Jews subjected to discrimination abroad, defended Jews accused of ritual murder at Damascus in 1840, lectured before the Rumanian parliament on liberalism and the Jewish question and effected the emancipation of Algerian Jewry. In addition he inaugurated a philanthropic and educational program to westernize (which in practise was from a Jewish point of view to denationalize) and fit for full citizenship in liberal national states the Jews of eastern Europe and the Levant and to secure their emancipation. In order to further this program in 1860 he helped establish the Alliance Israélite Universelle, of which he was president for sixteen years, and called for international Jewish support. Despite opposition from Jews in England, Austria and Germany who feared for their local status, he made it an effective instrument.

Crémieux' general political views and his Jewish interests were intimately related. His special status as a Jew made him an unusually liberal bourgeois lawyer, his liberalism defined his Jewish attitudes even to making possible the baptism of his children. While his Jewish achievements are less significant than those of a Mendelssohn, his political than those of a Lassalle, the combination makes him a classic example of the west European Jew at the flood tide of nineteenth century emancipation.

CRÈVECOEUR, MICHEL-GUILLAUME JEAN DE (1735-1813), Franco-American essayist. Crèvecoeur was born near Caen in Normandy of an aristocratic family and was educated partly in England. He served under Montcalm in New France and between 1759 and 1769 traveled widely in the English colonies. From the latter year until 1778 he lived the life of a small farmer in Orange county, New York. Because of his loyalist sympathies he became a refugee in New York City in 1778. Two years later he was permitted to return to France, where he remained until the end of the war. He was French consul at New York from

1783 to 1790, when failing health compelled him to leave America for the last time. His later years were spent for the most part in retirement.

Crèvecoeur's significance for his own age has several aspects. He gave to Englishmen and Frenchmen through the two books published during his lifetime a pleasantly written and accurate description of American fishermen, farmers and frontiersmen. The *Letters from an American Farmer* gave its author a place, although a minor one, among American men of letters. As consul at New York during the period of reconstruction which followed the revolution Crèvecoeur was active in a significant movement to improve American husbandry. Visioning the development of the republic as an agricultural and commercial nation such leaders as Robert R. Livingston and George Washington turned for counsel to England, where an agricultural revolution was under way. Crèvecoeur, throwing himself enthusiastically into the new movement, sought to bring French influence to bear on American agricultural thought. He assisted in introducing sainfoin, lucerne (alfalfa), the vetches, *vignon* and *racine de disette* to American agriculturists. He aided the American scientific pioneers who were establishing botanical gardens. Over the signature Agricola he addressed through the press a series of letters to American farmers.

The suppressed writings published in 1925 have made possible a clearer understanding of Crèvecoeur's mind. The farmer essayist had a deep sympathy for the common people while he remained at heart an aristocrat. His description of the struggle against nature of the American husbandman is the work of a man who was almost equally interested in natural and social phenomena. His discussion of the rewards of life for the independent American farmer is part of a philosophy which seems to have had its origin in a desire to escape from the artificialities of French life. A further development of the Crèvecoeur philosophy of life may be found in the essay *Liberty of Worship*, describing the religious vagaries of an American frontier community where no established church exercised a restraining influence.

The American Revolution stirred Crèvecoeur. He was impressed by the tragedy and moral desolation which it brought to the common people. He recorded the sufferings of patriots and loyalists alike. Mercilessly he portrayed the baser motives of many patriots of the less privi-

leged class in a vigorous and unfinished dramatic piece called *American Landscapes*. For the twentieth century investigator of social history Crèvecoeur's writings make available an almost unique picture of the life in peace and war of the common people of the northern provinces in the second half of the eighteenth century.

CRIME. A social group, small or large, possesses a vast number of beliefs, traditions, customs and institutions which are implicitly accepted by its members as relatively immutable and as conducive to their well-being. Conduct which is believed to be in accord with these beliefs, traditions and institutions is praised and encouraged as socially beneficial, while that which is believed to threaten or to injure them is condemned as antisocial. The conformist participates in the rewards distributed by the group for desirable conduct and the nonconformist is brought into line by coercion which ranges from mild disapproval and ridicule to threats of expulsion from the group or of extinction.

Antisocial conduct may be regarded as a universal phenomenon, a function of group life; but the extent thereof, the particular forms it takes and the nature of the reaction it provokes are variables which are intimately dependent on the cultural status and the social organization of the group. In some social groups today theft, infanticide, cannibalism, killing a policeman, cheating at cards or selling stock backed by imaginary assets are considered good and praiseworthy conduct. In other contemporary groups some or all of these activities are more or less severely castigated.

In preliterate groups no conduct is more severely condemned than that which is believed to offend supernatural powers. Even such acts as breaches of the hunting rules are associated with magical and religious concepts and therefore partake of the nature of sacrilege. In modern times the Inquisition and the witchcraft trials are evidences of the strength of religious concepts. As late as the middle of the seventeenth century the Quakers who came to the Massachusetts colony were punished corporally and capitally as "blasphemous hereticks," and executions for the crime of sacrilege occurred in France a century later during the age of Rousseau and Voltaire. With increased knowledge of natural phenomena the social reaction to offenses against the deities has grown weaker, but even today the teaching of scientific theories which contradict the Scriptures is in many communities regarded as antisocial and in some states is even a punishable offense. Laws prohibiting blasphemy also remain on the statute books of many modern states and are still occasionally enforced.

In some preliterate groups the exposure of female infants and the burial alive of the old and infirm are held to be socially desirable forms of conduct. The taking of the life of an enemy under certain circumstances is today generally regarded as a meritorious act. In some groups it is also considered justifiable for a father to kill the seducer of his daughter or for a betrayed husband to kill his wife or her paramour or both. Private property is today held almost as sacred as life, and thrift is a social virtue. In some contemporary groups and in many primitive societies, however, hoarding is an antisocial act. Standards of good and of bad behavior are not constant; on the contrary, they are in a state of flux, some changing imperceptibly, others appearing, disappearing and reappearing with relatively great freedom, depending on the rate of social change. The greatest divergence of standards is found in comparison between the master and the slave, the conqueror and the conquered, the rural and the urban dweller, the capitalist and the worker, the old and the rising generations and even between the stages in the development of an individual's personality.

The concept of antisocial conduct has not been defined or developed to the degree of precision which would make comparative scientific research possible. The criminologist studies such conduct only in one of its mani-

festations, crime, assuming that crime is an adequate sample of it. Crime is a legal concept, although some writers have used the term indiscriminately to denote antisocial, immoral or sinful behavior. According to law crime is any form of conduct which is forbidden by the law under pain of some punishment. The extent to which crime and antisocial conduct may coincide depends on many factors. In preliterate society the tribal tabus and customs, which bind together relatively small groups with essentially common desires, perform in part the functions of a penal code. With the evolution of the state and the growth of governmental machinery for the regulation of social relations by force and the adjustment of conflicts between individual and group interests, the relative identity of crime and antisocial conduct disappears. This is especially true where the criminal law establishes norms of conduct for large and complex communities where social differentiation is great and the number of different and conflicting interest groups is very high. What the law calls crime is merely conduct which is declared to be socially harmful by the group or groups in a state which are powerful enough to influence legislation. The concepts of crime and of antisocial conduct may vary so greatly in a feudal society, where these groups are small, and in states where social life is highly organized and differentiated, such as in modern industrial democracies, that crime ceases to be a reliable index of antisocial conduct.

Treason, murder, certain sexual offenses and some serious offenses against property are fairly constant in the criminal laws of the world, with relatively similar definitions. The criminal law in the case of some of these offenses (felonies, crimes, *Verbrechen*, *delitti*) may furnish a good index to the standards of antisocial conduct current in the group. In addition to these offenses, however, the increasing complexity of social life has led to the creation by the state of a vast number of laws which strike at forms of conduct peculiar to some particular type of social organization. Roscoe Pound in his *Criminal Justice in America* has found in analyzing the criminal laws of Rhode Island that the revised public laws of 1822 defined 50 crimes while the title, "Of Crimes and Punishment," of the general laws of 1923 defined 212. More than half of the offenses that may be prosecuted by the state and punished by fine and imprisonment or both are contained in special laws passed since 1872 dealing with such problems

as the protection of workers in industry, the regulation of motor vehicle traffic, the regulation of selling of securities and of merchandise and the enforcement of liquor prohibition laws. He concludes that during the last hundred years the number of crimes for which one could be prosecuted in Rhode Island has multiplied by eight. This criminalization of conduct has come as a result of the social growth and differentiation of an industrial civilization. Many of these crimes are not considered antisocial by large groups within the state. The sale of intoxicating beverages, for instance, although a crime in the United States is not, as has been shown in recent political elections or referenda, considered as antisocial conduct by all groups. In the case of such offenses the usefulness of criminal law as an index of antisocial conduct completely breaks down.

There is a close relation between the cultural environment and the technique of crime. The thugs of India strangle their victims; any other method would be contrary to group custom. In some groups poison, in others the stiletto, the blackjack, the revolver or the machine gun, is used by the murderer. The professional safe blower is not only a product of a mercantile society but his technique has kept step with the development of science. Organized crime is no modern phenomenon, but it is in the contemporary United States with its highly centralized business enterprises, its mergers and its trusts that such crime has reached its supreme development by utilizing for its execution the techniques of modern business.

Inadequate as the legal definition of crime may be, a vast amount of data has been collected by those agencies which are entrusted with the enforcement and the execution of law. These data, mainly statistical, have been used by students for three main purposes: the determination of trends in crime, the determination of the composition and characteristics of the criminal class and the objectification of administrative processes. Of these only the first two will be discussed in this article.

The extent of crime in modern society and the trends evident in the various types of crime cannot be determined without examining the nature of criminal statistics. A very few nations have gathered statistics of crime for a century, some for half a century and most nations for only a quarter of a century or less. The statistics are gathered by official agencies which come into direct contact with the crime, the criminal

or both, and they make possible tabulations which mark definite steps from the occurrence of the crime to the final discharge of the convict. The earliest of these steps is the report of the offense to the police and the arrest of the suspect; one of the last is prison statistics culminating in statistics of discharge after punishment. On the basis of this or that step crime rates have been instituted to indicate the extent and the trend of crime in a given community, but the value of these rates as crime indices varies considerably with the type of rate used.

Criminal statistics deal only with recorded crimes, for in no society is it possible to detect all criminal acts committed. Even murder, which is perhaps the most difficult to conceal, is not always detected. Only a very small proportion of such offenses as burglary or petty theft are likely to reach the attention of the authorities, and the proportion of offenses against public order known to the police are probably extremely small.

If the rate used as an index of crime conditions in the community is to be of any value it must be assumed to remain in a constant proportionate relationship to those conditions. In general, it may be said that the value of a crime rate for index purposes is in inverse ratio to the procedural distance between the commission of the crime and the recording of it as a statistical unit. An index based on crimes reported to or known to the police is superior to others, and an index based on statistics of penal treatment, particularly prison statistics, is the poorest. But the very nature of the offense may render even the first type of index invalid. When the offense seriously injures accepted social values, is of a public nature and prompts the injured party to bring it to the attention of the authorities it is likely to afford the basis for a good crime index. If it is not considered serious, is private or secret or of such a nature that the victim wishes to conceal it, any index based upon it will be of doubtful value.

The human equation represented by those who enforce and execute the law must also be taken into account in the interpretation of criminal statistics. The police, the prosecutors, the judges and the pardoning authorities, to whom the application of the law is entrusted, are themselves the products of a given cultural milieu. The percentage of arrests to crimes in Cleveland fell from 38 in 1922 to 21 in 1929. The total complaints for principal major offenses in Baltimore fell from 11,261 in 1923 to 7950

in 1929, while the total arrests there increased from 5097 to 5153. In 1875 512.7 persons per 100,000 population in Pennsylvania were charged with crime in the courts and there were 86.6 convictions; in 1924 the corresponding figures were 483.5 and 248.4. In Indiana in 1908 77 percent of all arrests resulted in conviction, while in 1928 only 59 percent were found guilty. An annual average of 255.67 indictable offenses per 100,000 population was known to the police in England and Wales between 1900 and 1904, and 172.71 persons were tried for these offenses; in the period from 1922 to 1926 the corresponding figures were 298.12 and 158.71, showing diametrically opposed trends. These illustrations show that the efficiency of the agencies of the law and their administrative policies are important elements in determining the trends of recorded crime.

Finally, since changes in such factors as age, sex and race distribution in a population occur over a period of time, the statistical refinement of even the best crime rate is impossible unless the general population statistics of the community permit it.

Offenses reported to or known to the police have not hitherto been published except by a few countries or localities. Great Britain leads the world in this respect, and within the last few years Finland and the United States have followed its example. The United States, however, due to lack of mandatory power, relies entirely on the voluntary cooperation of police officials. The statistical data offered in this article are therefore drawn largely from judicial criminal statistics. Although both American and foreign data are given they do not permit of comparison. Statistics cannot be used in their present state, if ever, as indices of the comparative criminality of nations, due to great international variations in social conditions, legislative practices and administrative policies.

Only the most serious offenses against the law cause a stigma to be attached to the offender. Were it otherwise, the psychic burden of criminality carried by the average community today would be immense, for the multiplication of legal prohibitions has made it difficult for any one of its members to lead a completely law abiding life. Fortunately, the serious offenses compose but a relatively small part of the sum total of violations of the law. In Los Angeles, for instance, with a population in 1930 of 1,238,048 there were, during the fiscal year 1929-30, 9618 arrests for felonies, 50,901 arrests

for state misdemeanors, 10,540 arrests for violations of city ordinances and 247,083 traffic citations. Of major offenses reported to police departments of the United States in October, 1930, a typical month, 70.8 percent were larcenies, 18.3 burglaries, 5.8 robbery, 3.8 aggravated assault, 0.9 murder and manslaughter and 0.4 rape. In Massachusetts in 1929 there were 7508 arrests for offenses against the person, 14,143 for offenses against property and 184,348 for offenses against public order. During the same year in Canada 89.1 percent of the convictions were for minor offenses. In 1927, 161.39 persons per 100,000 population were tried in England and Wales for indictable offenses and 1,572.47 for non-indictable ones. In Italy in 1926 there were 502 charges per 100,000 population for thefts, 293 for assaults, 178 for defamations and insults, 104 for offenses against public order, authority and trust, 79 for frauds, 13 for robbery and allied offenses and 8.7 for murder and manslaughter. In Germany in 1927, 41.5 percent of those convicted of offenses against the law of the Reich were offenders against property, 35.8 offenders against state, public policy and religion, 22.3 offenders against the person and 0.4 offenders against public trust. In Japan in 1926 the police disposed of 668,644 minor violations by fine or detention, and courts of first instance found 47,451 persons guilty of violations of special criminal laws, such as health and industrial laws, and 104,368 of violations of the criminal code, the last group including 62,317 gamblers.

Recent decades have seen a tremendous increase in minor offenses against public order, a fairly general increase in offenses against property and a reduction in violent crimes. The World War and the demobilization period caused great social disturbances, which were reflected in temporary increase of crimes against property in particular and also in offenses against trust, such as frauds and embezzlements. While the crime rates in most countries show much parallelism, a consideration of the data indicates great divergences. Indictable offenses known to the police in England and Wales decreased from 448.75 per 100,000 population in 1857 to 298.12 in 1922-26; the lowest figure, 251, was reached in 1915-19 and the highest since 1885 89 in 1922-26. The number of persons tried for these offenses fell uninterruptedly from 276.76 in 1857-66 to 158.71 in 1922-26. Of indictable offenses known to the police, from 1900 to 1926 a considerable in-

crease is noted in burglaries, larcenies, sex offenses and frauds; the greatest decrease occurred in offenses against the person. In the case of persons tried for non-indictable offenses the period from 1857 to 1866 showed an annual average of 1788.51 per 100,000 population, which rose to 2331.43 in 1872-76 and fell to its lowest figure, 1457.43, during 1915-19. The rate for 1922-26 was 1481.02. The fluctuations were largely due to corresponding changes in the rate of assault, which fell from 419.70 to 88.21. Malicious damage offenses also dropped from 86.42 to 38.69, and thefts from 59.98 to 9.12. On the other hand, offenses against highway acts rose from 42.57 to 498.10.

In Germany during the period 1882-86 the annual average of persons convicted for offenses against state, religion and public order was 119 per 100,000 population of punishable age. The corresponding figure for 1923-27 was 358. The number of those convicted for offenses against the person fell from 377 to 261, while the figure for offenses against property rose from 505 to 751; woundings, assaults and petty thefts showed a significant decline. A slight increase was noted in the homicide rate, and a great increase in abortions, frauds and forgeries. The years 1918-25 showed a temporary abnormal rise in convictions for practically all offenses.

In Japan the number of convicted offenders rose from 262.7 per 100,000 population in 1882-86 to 413.9 in 1892-96 and fell to 152.2 in the period 1922-26.

In Norway the number per 100,000 population convicted on felony charges fell from 177 in 1872 to 115 in 1907 and after a rise to 314 in 1918 fell to 139 in 1926. The misdemeanor rate rose from 942 in 1872 to 3020 in 1916 and has fluctuated in later years at a little above 2000.

In Canada convictions for serious offenses rose from 206 per 100,000 population in 1876 to 395 in 1914, fell to 231 in 1917 and again rose to 359 in 1929. Of these offenses those against the person declined from 125 in 1876 until the end of the century, then rose to a peak of 157 in 1914 and reached a new low, 81, in 1922. Since that time a gradual increase has been noted; in 1929 there were 106. During the period in question convictions for offenses against property rose from 78 to 212, the highest figure of the series. Convictions for minor offenses increased steadily from 508 in 1876 to 2928 in 1929. The greatest increase from 101 to 1850 was noted in offenses against the municipal acts and by-laws. Convictions for

liquor law violations and drunkenness rose from 318 to 593, the year 1913 showing the high peak of 889. The conviction rate for both major and minor offenses rose from 714 in 1876 to a climax of 3286 in 1929.

In the United States no nation wide judicial statistics exist, and while national police statistics are now being collected they are of too recent origin to be of any value for comparative purposes. One is forced, therefore, to rely upon statistics from a few states. In Massachusetts, which alone publishes state wide arrest figures, the total number of arrests rose from 106,428 in 1903 to 205,999 in 1929. The population of the state increased from 2,805,346 in 1900 to 4,250,104 in 1930, indicating that the rise from 11,465 to 14,143 in the total arrests for offenses against property represents a relative decrease per population unit. Arrests for crimes against the person fell from 8260 to 7508 and those for crimes against public order rose from 86,703 to 184,348, a relatively great decrease and increase. In Connecticut, which publishes annual statistics of prosecutions, the gross number for sex offenses increased from 59 to 207 between 1904 and 1928. Prosecution for offenses against property rose from 489 to 559; murder and manslaughter cases increased from 23 to 37, and assault cases dropped from 244 to 143. Cases of breach of peace and similar offenses rose from 96 to 233, drunkenness and vagrancy from 180 to 325, and motor vehicle violations from none to 498. The total of prosecutions increased during that period from 1316 to 2259, while the population increased proportionately from 908,420 to 1,606,903 in 1930. The peak of the total gross rate was reached in 1925, and that for serious offenses was reached in 1917. The peak of prosecutions for liquor law violations came in 1924, and motor vehicle offenses have been steadily rising.

In Indiana one out of every 53 citizens was charged with a criminal offense in 1908; in 1928 one out of 35. During these decades felony charges rose 103 percent and misdemeanor charges 46 percent per population unit. The charges of robbery, burglary, rape, assault, homicide and larceny altogether increased 54 percent, the greatest increase occurring in the first and the smallest in the last mentioned offense.

In New York state the annual average of felony convictions per 100,000 population in 1903-07 was 60.06. This figure rose to 87.03 in 1913-17, fell to 76.68 in 1918-22 and in-

creased slightly to 77.34 in 1923-27. During these periods convictions for offenses against the person steadily increased from 11.1 to 16.8, while those against property fell from 36.49 to 26.44. Intoxication convictions rose from 204.96 to 290.20 in 1913-17, fell after the war to 117.74 and rose in the last five-year period to 143.53. Convictions for misdemeanors rose steadily from 177.46 to 372.84, while convictions for minor assaults, thefts, vagrancy, liquor and tax law violations fell from 164.5 to 81.0. The rate for convictions as a whole rose from 607.5 to a peak of 792.92 during 1913-17, fell to a low point, 503.34, in the subsequent period and increased to 674.66 in 1923-27.

In Pennsylvania total convictions per 100,000 population fell from 86.6 in 1875 to 66.1 in 1910 and then rose rapidly to 248.4 in 1924. Comparing merely the first and the last years of the series, convictions for offenses against the person are seen to have risen from 22.9 to 27.2, those for gainful offenses against property from 32.5 to 71.1, for offenses against sex morality from 8.0 to 19.1, against the administration of government from 1.5 to 5.2, against public health and safety from 1.1 to 23.3, against sobriety and good order from 6.9 to 8.3 and against public policy from 7.0 to 76.9. The only decline, from 2.8 to 0.2, occurred in gainless offenses against property.

In California the number of persons per 100,000 population charged with criminal offenses rose from 251 during the two fiscal years 1904-06 to 367.6 in 1914-16 and 435.1 in 1924-26. The corresponding figures of persons convicted were 156.8, 246.6 and 241.4. The increase appears to have been largely in minor offenses, since the average number of persons per 100,000 population sentenced to institutional punishments was 133.7, 143.4 and 145.5 respectively.

In Iowa from 1849-1927 the rate of convictions for criminal offenses per 100,000 population by five-year periods rose from 92 in 1850 to 557 in 1925. The high peak of 502 was reached in the five-year period 1873-77, after which a steady decline occurred to 254 in 1908-12. For the 1901-26 period, during which the population rose from 2,231,853 in 1900 to 2,419,927 in 1925, the gross number of felony convictions increased from 471 to 831, while those for misdemeanors rose from 758 to 2596. Of the total number of 1229 convictions in 1901 liquor offenses accounted for 95 and automobile offenses for 1. In 1926 out of a total of

3427 convictions the corresponding figures were 989 and 482.

Claims have been frequently made that since the World War the United States has been engulfed by a crime wave. The data cited above do not wholly support these claims; except where this wave reached its peak during the war years it began before the war and is still rising. In many of the states studied, recorded serious crimes have been declining since the war, but the increased use of motor transportation and the passage of the Eighteenth Amendment have contributed to a mounting rate of minor offenses against public order. Public agitation, which has expressed itself in a wave of ill considered repressive legislation, may be due to an increase in professional crime which unfortunately is not measurable by the aid of present criminal statistics. The current belief in a crime wave may perhaps be understood if one considers the publicity which has been provoked by the spectacular nature of modern organized crime and the sinister shadows it has thrown on the agencies of law enforcement.

Criminal statistics have also been used to throw light on the composition of the criminal class. It is difficult to say to what extent the criminals who are arrested, convicted or sent to prison, particularly the last group, are fair samples of the criminal class. Statistical data from judicial and prison sources indicate that in most countries today crime is largely committed by youths, the age groups from 18 to 25 yielding the highest proportion of offenders, particularly in crimes of violence. Here again the nature of the criminal law must be taken into account. In Japan, for instance, the age groups from 30 to 40 show the highest conviction rate, probably because over half of those found guilty are gamblers. There are more male than female recorded criminals; the proportion is approximately 9 to 1, although the entrance of women into occupations hitherto closed to them is tending to increase their recorded crime rates. Rural areas seem to contribute less to criminality than do urban districts, and it is apparently from the lower social ranks of the urban dwellers that most apprehended criminals are recruited. The relatively high recorded crime rates of Negroes, emigrants and economically unfortunate people are no doubt artificially raised by such factors as prejudices against races or nationalities and the inability to obtain competent legal advice.

The desire to find a rational explanation of

crime has led to the development of a host of theories about its origin. Evil spirits, sin, disease, heredity, economic maladjustment and a number of other causative factors have been advanced, singly or together. The growth of science has tended to discourage monogenetic explanation of human conduct, and today most criminologists adopt a frankly eclectic viewpoint, although some of them are inclined to lay greater emphasis on heredity, others on environment. As the social sciences have thrown into bolder relief the cultural determinants of personality, many behavior forms which were assumed to be biologically determined have become adequately and perhaps better understood in terms of the social situation. The high rate of crimes of violence in south Italy has frequently been explained in terms of racial inheritance, as has the high homicidal rate of the Italian immigrant in the United States. It seems to have been adequately proved, however, that the Americans born of south Italian parentage show a criminal distribution much more like that of the native stock than that of their parents. The low Jewish crime rate, particularly for crimes of violence, has frequently been explained on a racial basis, but it would be difficult to interpret the high crime rate of the Jewish diamond cutters of Amsterdam except in cultural terms. The individual's biological capacities for development must express themselves through social life which constantly molds and directs the process of expression. Antisocial conduct and crime are likely to flourish in heterogeneous groups where rapidly changing and conflicting standards of conduct exert a disorganizing influence upon the personalities of their members.

The existence of crime in a community is a challenge to its members, for on the whole its effects on ordered social growth may be regarded as deleterious. The waste in misdirected energy and the economic burden are enormous. It has been asserted, however, that to some extent crime serves a useful social end; that it creates solidarity in the group which is injured by it; that it is essential for the maintenance of a moral code; and that in some forms of crimes one may see the signs of a new morality which in the future will govern social relations on a higher ethical plane. There is undoubtedly a measure of truth in these claims. On the other hand, it may be said that the solidarity of the law abiding group provokes in turn an opposing solidarity in the criminal group; that while good

behavior and bad behavior are essential correlates, a relatively small amount of the latter will suffice to provoke a social reaction; and that the concept of the so-called evolute crimes is largely based on retrospective rationalization.

The progress of the sciences of human behavior has in recent decades increasingly centered attention on criminal behavior. The last half century has seen the beginning of a criminological science, and official and private agencies for the study of the criminal and his treatment have been rapidly multiplying. The disastrous results of the World War have caused most countries to realize that a new orientation of penal agencies is necessary. In Europe many countries have already reformed or are in the process of reforming their criminal codes and penal administrations, and in the United States the work of the American Law Institute and of numerous state and local crime commissions testifies to the growing belief that the task of dealing with crime is one which demands a knowledge of facts upon which an intelligent program of study and treatment may be constructed.

A recent bibliography is that of the Social Science Research Council, Committee on Survey of Research on Crime and Criminal Justice, *A Guide to Material on Crime and Criminal Justice*, prepared by A. F. Kuhlman (New York 1929).

CRIMINAL LAW may be defined as the body of precepts and practises which a community employs to protect itself by the use of force against acts which impair or endanger its internal peace and security. No human community has yet been found which has lacked such precepts and practises. All law is a growth, a matter of accretion and of development out of custom and habit. This is as true of the law embodied in the Mosaic and Babylonian codes and in the Twelve Tables of Rome as of that which is usually called the customary law. For this reason no scientific study of the law of today can be justified, nor can modern law be accounted for without harking back over the trail of its history to its beginnings. But the beginnings of modern European and American law in what is known as "primitive law" are undiscoverable. The cave man—if he was, indeed, the ancestor of modern man—left no legal records on the walls of his cave. Even Maine's *Ancient Law* goes back no further than to what he calls the "era of codes," of which the Twelve Tables of Rome were the outstanding example, and the code admittedly belongs to a relatively advanced stage in social and legal evolution. Even Maine's reference to the trial scene described by Homer as pictured on the shield of Achilles remains far short of primitive law. The same picture, under the name of the "blood feud," is found in mediæval codes. It is possible that certain obscure Sanskrit texts may yet be translated and throw light on the problem:

but in the meantime, although direct evidence is lacking, there are certain clues as to the origins of law. These are found in comparatively recent, first hand studies of contemporaneous primitives, such as certain Eskimo tribes, the Indians of North America, the inhabitants of Samoa and of other Pacific islands and some African tribes. If it may not be assumed that these people are, in their mental and social characteristics, much like the primitive ancestors of modern man, there are in fact to be found in their present social attitudes and practises many of the reactions and procedures which found expression in the codes from which modern criminal law derives.

Primitive Law. The first thing that strikes one in contemplating these diverse groups of primitives, with their wide diversity in social organization, is the emergence of similar methods of dealing with an offending member. In some groups there is no headman nor tribal organization nor anything that savors of a court of justice. The law, which is nothing but custom, is rarely violated and, when violated, may in extreme cases be self-executed by the voluntary exile or the suicide of the offender; more frequently he is subjected to public humiliation. Among other tribes, however, the offender, if recalcitrant, may be brought before the headman or the council of elders—not for trial, in the modern sense of the term, but for judgment. His guilt is known or assumed. The only question is as to the measure of punishment to be suffered and this is usually fixed by custom but may be modified by bargain, except where the injured party or his group insists on full payment. The latter case, indeed, leads to the threshold of the blood feud, which plays a major part in mediaeval law. The identification of the individual with his group is so close that a crime, for example a killing, committed by a member of one group (which may be a tribe or village community of considerable size, all the members of which are bound by ties of blood) on a member of another group, becomes a group offense and any member of the injured group may, unless due compensation is made, retaliate on the offender's group by killing any member of it. The compensation to be paid is determined by the social importance of the victim of the crime. For a crime committed within the group the death penalty is rare and is inflicted only for the violation of a tabu, as incest. But there is no "strict law" in the modern sense of the

term. Nearly every legal liability, even for the violation of a tabu, if not too aggravated, may be compromised or waived.

The most striking, as it is the most obvious, fact in primitive life is the insignificant role of law, even of customary law. Maine notes the strange preponderance of criminal over civil law in rude as compared with mature jurisprudence. But this is due not to the magnitude of the criminal law but to the all but complete absence of civil law in a kindred community where property and personal relations are of the simplest and are automatically regulated by custom. One may go further and accept the conclusion of Lowie and other recent students that, however minute the regulations as to individual conduct might be in primitive society, they were rarely violated. So compelling is custom in such a closely integrated community—for every custom has a sacred character—that it may be believed that primitive society was far more law abiding than any modern community has managed to be.

What may be described as the second stage in the development of criminal law is perhaps best represented in the Visigothic, the Anglo-Saxon and other Germanic codes which form the immediate background of the criminal law of western Europe. The law embodied in these codes has come down only in fragmentary form but enough survives to demonstrate their heritage from the more primitive law which preceded them. What they disclose is the primitive practise of compensation, elaborated, systematized and enforced by the legal authority of the state in the interest of the injured party. This is most clearly shown in the Anglo-Saxon law under which, as Kemble writes, "a sum was placed on the life of every freeman according to his rank" (this was the *wergild* or man-price of Anglo-Saxon law) "and a corresponding sum on every wound that could be inflicted on his person, for nearly every injury that could be done to his civil rights, his honor or peace." But this, as Maine points out, is not in the modern sense of the term a true criminal law but a law of delict or tort. A crime is an act which violates the peace and dignity of the state, which the state punishes for its own protection in the general interest and which accordingly cannot be waived or condoned by the individual who happens to be the sufferer from it or by his immediate kin. A tort is a personal injury with which the state has no further concern than to see to it that the injured party or his kindred receive due compensation. This principle of

compensation was, in the society out of which it emerged, an essential device to avert the devastating consequences of the *lex talionis*. The same end was later more effectually attained by the development of a true criminal law in which the interest of the state in the common security became the dominant, if not the sole, factor.

While this result was not fully attained until what may be called the historical period, it is not to be assumed that the community, however primitive, was ever indifferent to the common weal. Public and sacral offenses are so dangerous that collective action has to be taken against them. This has been noted above in the group punishment of certain offenses, such as the violation of a sacred tabu, which was essential to the integrity of the community as a whole or protected it from the vengeance of the deity. So parricide or matricide, or an attempt at the usurpation of authority over the tribe or any one of a variety of offenses recognized as atrocious sins against the deity was summarily punished, almost invariably by death. These may well have been extremely rare in primitive society but with the development of the larger, less integrated community they became frequent enough to call for more drastic repression. It was doubtless the predominantly religious character of the Israelitish and Babylonian codes that caused the prescription of the death penalty for a variety of offenses denounced by the tribal deity which, in the western world, were more leniently dealt with.

In a mature criminal law the intent to commit the criminal act, the *mens rea*, is an essential element in guilt. This is, however, totally lacking in the conception of crime in early law. In the blood feud it is not to be expected that the avenger will pause to determine whether the homicide was premeditated. Thus, too, the composition was payable whether the deed was wilful or accidental. It marked a great mitigation in sentiment when, as in the Mosiac law, cities of refuge were provided to which an offender who had killed someone inadvertently or otherwise without malice might flee and thus escape the avenger of blood. Primitive society had no penalties but death or exclusion from the community and the latter, as Cain reminded the Almighty, was the equivalent of death. The principle of exact retribution—an eye for an eye, a limb for a limb, a life for a life—which we find in some of the earlier codes, was an obvious mitigation of the earlier uniform rule of death

for all offenses of a serious character and marks a distinct stage in the long process of supplanting private vengeance by public law. But traits of self-help survive long after orderly retaliation has become established. It is evident directly in the hue and cry of the Germanic law, in the throwing of offenders from the Tarpeian rock in ancient Rome. The greater license in dealing with an offender caught in fresh pursuit is readily understandable on the basis of private vengeance. It was less likely to be restrained in such a case. The right of self-help is to be seen indirectly operative in the increase of the fine allowed at a later stage in the case of a thief caught in the act. Thus in the Roman law the penalty in the case of *furtum manifestum* was doubled. (The Twelve Tables had provided that a thief caught in the act might be slain but the law had been changed by praetorian edict.) This was not at all because detection in the act was an aggravation of the offense; the increased penalty was intended to induce the injured party to refrain from taking the law into his own hands.

State Law. The assumption by the state of the right and the duty of punishing criminal offenses was generally a long and uneven process. It began as a legislative or as an executive rather than as a judicial procedure. Dangerous malefactors, aiming at unwarranted power or themselves too powerful to be dealt with by the ordinary community processes, could be reached only by the arbitrary action of the king or by a special bill of pains and penalties duly enacted by the legislature. Attainder is the term by which this process was known in England. It was employed in Athens in the classical era and later in Rome, in the Anglo-Saxon kingdoms and finally in England. Maine asserts that the earliest criminal tribunals were only subdivisions or committees of the legislative assembly appointed to investigate and report on a given case and that these in the long course of time became standing committees to try all offenses of a given type, as parricide, for example, and ultimately all criminal offenses.

In Rome the process employed in the exercise of criminal jurisdiction was the clumsy one of creating committees to inquire into all cases of a given type, the so-called *Quaestiones perpetuae*. For other types of offenses which seemed to need repression other *Quaestiones* were created or the jurisdiction of an existing *Quaestio* was enlarged to include the new offense. In this

haphazard way the system developed until, as Maine declares, "twenty or thirty different criminal laws were in existence" (comprehending, it may be assumed, a far greater number of criminal offenses) "together with exactly the same number of legislative commissions, *Quæstiones*, to administer them."

Notwithstanding the awkwardness of this procedure and the resulting lack of symmetry in the criminal law of the republic, it gave permanent expression to two pregnant conceptions which have ever since governed the thought and practise of the civilized world. The first of these is that it is the function of the sovereign legislature to define by law the crimes of which it will take cognizance, and the second that it is the function of the governing authority of the state to enforce the law so enacted. The empire, which soon succeeded the republic, had no need to usurp the authority to define and administer the criminal law of Rome. It had only to take it over, and with its expansion it carried these conceptions to the ends of the world.

In all matters not involving the imperial supremacy the Roman governors in the provinces, whether of the East or of the West, were wise enough to administer the imperial law in reasonable conformity with the local custom. This was, indeed, the policy of the empire and accounts in large measure for its success in maintaining itself for so many centuries in communities representing wide diversities of culture and of political development. But the law of Rome was a system far more developed than that of any of the provinces and its imperial prestige gave it immense influence. For these reasons the Roman law profoundly, although in varying degrees, imposed itself on the local law, in its precepts, in its organization and in its authority. The princes that took over the lordship of the provinces after the withdrawal of the legions found themselves invested with much of the glamour of the imperial lordship and, as the emperor's successors, were easily recognized as the guardians and dispensers of justice.

It is not easy to say to what extent the criminal law of the provinces of the empire shared in this Romanizing influence except in the matter of promoting the centralizing processes of law making and of law enforcement. The influence varied greatly according to the longer or shorter duration of the Roman occupation and the stage of social development of the subject population. Spain appears to have been

completely Romanized and France and Belgium only less so. The more remote and perhaps more backward Germanic tribes were far less affected in their customs and consequently in their criminal law and the English hardly at all. But all the countries that had felt the iron hand of Rome had learned the worth of centralized power to hold a fruitful realm in awe.

In England, however, there was another conception at work, which might, without the help of Rome, have developed a national criminal law: the doctrine of the king's peace. The royal court and its environs were of course under the king's exclusive protection but he could extend his "peace," the pledge of his protection, to any person, a bishop or a nobleman, or to any place, a church or a town, at his pleasure. He thus assumed the responsibility of dealing with any serious breach of the peace that might be committed against such person or in such a place. So the king's peace grew until it was extended to the whole of England, to all his dominions, and the king became the fountain of justice to all his people.

This conception was naturally taken over by the American colonies when they achieved their independence and thus the new national government, in the limited field in which it exercised a criminal jurisdiction, and the several states, in their more general control of criminal misconduct, set up the same centralized system of criminal law and procedure on the principles to which their experience as colonies of Great Britain had accustomed them. It is true that in the expansion of the new nation into regions to which the law had not yet been effectually applied there was, here and there, something like a reversion to primitive justice. Where there is no overruling state law the law of self-help revives. But these cases were only sporadic and have left no trace on the legal structure, although they may in part account for certain traits in the American character which make for a casual indifference toward the law and a rough lawlessness in methods of law enforcement. So indictments today read that the offense charged was committed "against" or "contrary to" the peace and dignity of the state and, although there are still torts, every offense committed with malice prepense is a crime and the law defining it and prescribing the penalty therefor is a true criminal law.

Civil and Canon Law. The influence of Rome on the law of the western world did not end with the decline and fall of the visible empire.

That was succeeded by a new and greater empire which claimed, it is true, only a spiritual authority but which enforced that authority by stringent secular penalties. Both the growth and the authority of the law of the church, which came to be known as the canon law, were promoted by the legal chaos which resulted from the barbarian conquest of the Roman world. Law became personal or tribal rather than territorial. The barbarian lords, in Italy as elsewhere, ruled over a mixed population and there was one law for the *Romani* and another for the *barbari*, as the Burgundians or the Ostrogoths. The only unity in Christendom was that of the church and the only universal law was the law of the church. The concept of a single law, both Roman and Christian, ruled the imagination of Europe for many centuries; and so it came to pass that the canon law vied with the law of the empire, the collected "constitutions" of the dead emperors embodied in the civil law, as the chief study of the scholars of western Europe. Both these codes profoundly affected the criminal law of the western world. Striking evidence of the influence of the canon law in England is furnished by the savage punishments inflicted, not in the name of the pope but of the English king, on sorcerers, soothsayers, witches and heretics and in the curious provision of the criminal law exempting "clerks," i.e. clerics, from the punishment of death for felony. Blackstone, writing in the middle of the eighteenth century, opens his enumeration of the crimes punishable by English law with a list of eleven specific "Offences against God and Religion." Doubtless it was the penitential doctrine and practise of the Anglican Catholic church that inspired the shocking provision of the English and American criminal law which fixes the age of responsibility to its procedure and penalties at seven years.

The Growth of Law. During the long period of history that has just been reviewed the substance of the criminal law, the precepts defining prohibited misconduct and prescribing the penalties therefor, changed with the mutations of the social order. Theoretically law is still custom, a thing to be recognized and defined, not something arbitrarily imposed by sovereign authority. But custom is not, as it was in the primitive community, a uniform body of folkways, all but universally conformed to. Modern society is a congeries of customs, habits and practises of widely differing groups and social classes. For "custom" is now written "public opinion," but there is no one uniform public

opinion in any modern community. Even in the Roman Republic there was one public opinion of the equestrian order, represented by the *Comitia Centuriata*, and another of the plebeian order, represented by the *Comitia Curia*. When power shifted from the former to the latter the spirit and complexion of the criminal law underwent a marked change in the direction of a greater leniency. So in the England of the Stuarts and the Georges, the excessive severity of the criminal law persisted until the growing power of the Commons reformed and humanized it. So too in France it was the people's revolution which, to even a greater degree, mitigated the severity of the *ancien régime* in dealing with the common offender. Similar mutations of feeling and attitude have been displayed in the United States toward the criminal offender in response to waves of democratic or of conservative opinion.

Subject to the fluctuations of public opinion above described there is a singular uniformity in the substantive criminal law of most of the peoples comprising the civilized world. The old crimes of murder, robbery, burglary and the like, which were the staples of the law of the eighteenth century, are still dominant in the criminal codes, but with the development of a predominantly industrial and commercial civilization the emphasis has in varying degree shifted from Blackstone's felonies and misdemeanors to the much greater number and variety of more modern crimes of the acquisitive type. These have, indeed, increased the volume of criminal legislation to such a degree as to render the problem of law enforcement today far more complex and difficult than it was even a century ago. Coincidentally with this development there has, particularly in the western world, been an immense increase in the number and variety of petty offenses not involving serious moral turpitude which, under the complex conditions of modern life, demand legal repression. This disposition to regulate by law types of conduct formerly left to be dealt with by informal social pressure is, more in the United States than elsewhere, still further extended to a multitude of cases in which the community seeks by legal penalties to protect the general welfare by social legislation respecting health, the sale of habit forming drugs and of liquors, and the like.

The Code. But if the criminal laws of the several states of the civilized world display, as has been said, a marked uniformity, it is not to be inferred that the summaries or codes in which

they are collected have a characteristic form or any considerable resemblance. Reference has been made to the chaotic condition of the criminal law which evolved during the later period of the Roman Republic. Nothing was done then or under the empire to simplify or classify the heterogeneous mass of criminal statutes. The constitutions of the emperors now appeared as the only active source of law and these constituted a disordered mass, to be collected rather than digested. Dicey, speaking of a much later era, remarks that "the classification of crimes which are contained even in the *Corpus juris* of Justinian are remarkably capricious." This is notoriously true of all of the earlier codes, whether Hindu or Babylonian, Israelitish or Greek or Saxon, which were a compound of religious and moral maxims with a miscellaneous assortment of crimes denounced and punishments prescribed. The French penal code of 1810 appears to have been the first compilation of criminal law to attempt anything like an orderly arrangement and classification of crimes and penalties and this, in its turn, was taken as a model for Edward Livingston's Louisiana code, *A System of Penal Laws*, largely deriving from the Spanish as well as from the French but predominantly Anglo-American, which greatly bettered its example and, indeed, furnished a model for the better type of legislative codes which are now in the making in western Europe and the United States.

Perhaps too much has been made of the importance of classification of criminal offenses. That some orderly statement of the body of the criminal law should be made for the purposes of the student is obvious but this is not to say that it will have any value to the legislator, the judge or the practitioner in the criminal courts. For these the alphabetical arrangement of the New York criminal code, which begins with *abduction* and ends with *woman* (abduction being a crime and woman the possible victim of crime), absurd as it may seem, may be the most convenient. Blackstone's classification of crimes from their object—as crimes against the state, against the person, against property, against public morals, etc.—has a certain logical consistency which may be of assistance to the student, but serves no public purpose. This is the arrangement employed in the French code and by Livingston in his Louisiana code and it has been generally adopted in recent legislative codes as well as in modern treatises on the criminal law.

The English classification of crimes according

to their seriousness or their menace to the public weal, as felonies or misdemeanors, had practical value at a time when all felonies and no misdemeanors were punished with death. Today when the death penalty is imposed only for wilful and premeditated murder, for treason, piracy and a few other offenses of rare occurrence, and when the usual penalty for felony as well as for misdemeanor is a sentence to imprisonment, the distinction has all but lost its meaning. All felonies and most misdemeanors are indictable offenses and, with few exceptions, are triable only in the ordinary courts of criminal jurisdiction by a jury.

There remains in the British Commonwealth and in the United States a third class of offenses, ordinarily triable by summary process, by courts of petty sessions or by a local magistrate. In some of the American states the term misdemeanor is employed for cases of this type. Convicted petty offenders are punished by fine or by commitment for short terms to a local prison or jail. The only practical distinction between felons and misdemeanants in most states of the United States is that the former may be sentenced for a year or more to a state prison or penitentiary, while the latter may expiate their crimes by a sentence, usually of shorter duration, served in a less formidable type of prison. In the French *Code pénal* the division of punishable offenses is into *crimes*, *délits* and *contraventions*, which correspond roughly to the felonies, the indictable misdemeanors and the petty offenses of English and American law. These are in France dealt with by different tribunals, the first class by a judge and jury, the second class by a bench of three judges and the third by a *juge de paix*, or police magistrate. Substantially the same threefold classification of criminal offenses obtains in all other European countries.

The limited criminal jurisdiction enjoyed by the federal government of the United States has militated against the development of a criminal law calling for the graded classification which obtains in the several states of the union, although that classification is latent in the language of the federal constitution which guarantees the protection of a grand jury indictment to every person held to answer for "a capital or otherwise infamous crime." In the District of Columbia and in the limited territories which are administered directly by federal authority the central government has enacted criminal laws and set up a machinery for their administration substantially like those of the several

states. Apart from these rare cases of territorial jurisdiction the criminal legislation of the federal Congress has to do almost exclusively with offenses arising out of the violation of income tax, tariff, bankruptcy and national banking laws and the like and, more recently, with the enforcement of national prohibition of habit forming drugs and intoxicating liquors. But most of these are of the class of offenses against the state and show too little variety in type or character to fit into any formal scheme of classification.

Fundamental Principles. Out of this heterogeneous mass of prescriptions, written or unwritten, which make up the criminal law of the western world, there emerge a few general principles in the nature of limitations on arbitrary power, whether of the sovereign or of the law itself. The most important of these, inherited by the United States from the English law, may be stated in the language of the Bill of Rights of the American constitution, viz.: that no person shall "be deprived of life, liberty or property without due process of law," "nor shall any person be subject for the same offense to be twice put in jeopardy of life or limb"—a provision which has been extended to every type of penalty for crime. Analogous to these are the "rule of certainty," which prescribes that every act made punishable by law shall be so clearly defined as to leave no penumbra of uncertainty as to its applicability to a given case, and, finally, the rule denying any retroactive effect to a penal law. The last of these, embodied in the maxim *nullum crimen nulla poena sine lege*, was the first rule laid down by Livingston in his draft codes for Louisiana and the United States.

There appears to be no warranted derogation from these principles in any modern state except in the Soviet Union, where an act deemed socially dangerous, although not specifically denounced by law, may be punished on the ground of its analogy to conduct prohibited by law. Further constitutional guaranties of English and American law to the effect that no one shall be held to answer for a capital or other infamous crime unless on a presentment or indictment of a grand jury, and that no person shall be compelled in any criminal case to be a witness against himself, seem to be peculiar to the Anglo-American system.

It is the rule of certainty which has caused the modern tendency in America to embody the criminal law more and more completely in

statute form. As has already been observed, the criminal law of the later years of the Roman Republic and, even more completely, that of the empire were built up by legislation. This has continued to be true of the European countries that were most profoundly affected by the Roman tradition. It is only in England that this influence was rejected and that the law, criminal as well as civil, continued, as it still continues, for the most part, to be a common law, whose principles and prescriptions are formulated by judicial decisions; and it was this common law which became the heritage of all but a few of the American commonwealths. But a common law is a matter of slow growth and, in a modern social order of increasing complexity, needs constantly to be supplemented by legislative enactments. Adding to this circumstance the further fact of uncertainty in the common law due to differences in judicial interpretation and the vagueness with which it is often infected, a sufficient explanation is found of the demand of the community for the certainty which is to be secured only through a legislative reenactment of the entire body of the criminal law. England has thus far successfully resisted this tendency but it has all but completely triumphed in the United States. In only a few of the states is the misdemeanor still left to the common law, while the felony is everywhere defined and punished by statute.

Procedure. Reference has been made to the substantial uniformity of the criminal law of the civilized world at the present time, but it is only in the substantive law that this condition obtains. In the matter of criminal procedure there is a marked difference between the theory and practise of continental countries and of those that owe allegiance to the English common law. The imperial tradition of Rome has to a considerable degree maintained itself in the former, while the latter still employ the more popular forms of procedure which had their origin in the Anglo-Saxon community. The archaic practises of the ordeal and of trial by battle were, indeed, widely employed as a test of guilt or innocence, but it is to English law that the United States as well as the British dominions owes the grand jury as an accusing body in cases involving grave offenses, and the petit or trial jury as the only instrumentality for determining the question of the guilt or innocence of the accused. It is true that the trial jury has, during little more than a century, come to be adopted in most if not all conti-

mental countries, but it is an official of the government, a prosecutor in fact, who conducts the investigation and becomes the accuser. The Anglo-American plan has this merit, at least, that it gives a semblance of reality to the presumption of innocence which invests the accused up to the moment when, by the unanimous verdict of the trial jury, he is convicted on evidence establishing his guilt beyond a reasonable doubt. The importance of these fundamental safeguards has been seriously impaired, although by no means wholly destroyed, by the growing power of the prosecutor in American criminal procedure during the last generation. As the official adviser of the grand jury he can usually secure an indictment in cases where he deems it necessary and he may, as *ex officio* adviser of the court, secure the dismissal of pending cases or the acceptance of pleas of guilty, usually in a lesser degree than the crime actually committed.

These conditions, which have exhibited the prosecutor as the principal factor in the actual administration of criminal justice in the United States to the virtual exclusion of the jury in by far the greater number of cases which it is its peculiar function to try, combined as they are with the uncasiness of the public over an excessive crime rate, have caused widespread dissatisfaction with the administration of criminal justice in the United States.

This dissatisfaction, predicated on the doubtful assumption that the problem of crime control is mainly one of procedural law, has found its most effective expression in the reaction of the legal profession. Under the auspices of the organized bar, surveys of the actual operation of the processes of criminal justice have recently been conducted in a number of states and cities and, what is of even greater significance, such a survey on a national scale, directed by a commission of eminent jurists and others appointed by the president of the United States, is now under way. These painstaking inquiries have indicated the existence of an incredible looseness and lack of efficiency in the administration of criminal justice in the United States, especially in the great urban communities, due not so much to defects in the law (these, indeed, seem almost negligible) as to the political and social influences which control the selection of the law enforcing agencies and determine their official action. This indictment of a system may be summed up with the statement of an obvious truth, namely that a community which is itself

indifferent to the law of the land cannot fail to find that indifference reflected in its administration of the law. In the conditions described the American community but displays the characteristics of a people which has, for better and for worse, not yet wholly outgrown its wild and turbulent youth, a stage of development through which the more staid and settled communities of western Europe have also passed. In so far as America is still the land of opportunity and high adventure it is likely to continue, along with a high crime rate, to manifest the qualities which reveal themselves in an attitude of superiority to law and of reckless indifference to law enforcement.

The Outlook. Reference has been made to the influence of a changing public opinion in stifening or mitigating the rigors of the penal law. Lecky remarks on the growing humanitarian sentiment of England, far behind that of the France of Rousseau and Voltaire, in the closing years of the eighteenth century, and it was to this new humanitarianism that Beccaria so successfully appealed in his argument against torture and the death penalty. This sentiment soon became a tide which, in the course of a half century, all but transformed the penal law and practise of the whole western world. But sentiment, however generous, is a parlous thing unless buttressed by doctrine, and Beccaria's doctrine, however acceptable to the intelligentsia of his time, was of the flimsiest sort, based as it was on Rousseau's social compact and arguing nothing more than the unfairness of a punishment which the criminal had not bargained for.

Beccaria had no quarrel with the fundamental concept of the criminal law of his time and of modern times, namely that of the moral responsibility of the offender. A criminal act is primarily sin. This accounts for the persistence of the retributive element in penal legislation and practise. Sir James Stephen, the historian of the criminal law of England, asserts with approval, the approval of a judge of the High Court of Justice, that "the criminal law is mainly a system of licensed revenge." What is more frequently asserted as the aim of punishment is its deterrent effect on the community at large as well as on the culpable offender. This doctrine, which received its most complete statement from Bentham, was the basis of Beccaria's argument for moderation but in practise it results in the infliction of "exemplary" punishments, such as will create dread in the mind of

the potential offender. A third aim of punishment, frequently claimed for it, is the reformation of the offender. Plato and the wide and powerful stream of philosophy which has flowed from his writings assume the reformation of the criminal as a mystical operation of retributive justice, like the penitential discipline of the Catholic church. But modern legislators and judges are not philosophers, and it is more likely that they will reflect the vindictive sentiments or the fears of an unphilosophical community.

This description of the processes which determine the type of present day criminal justice needs to be supplemented by a consideration of two antagonistic principles between which the actual administration of the law has oscillated. The first of these is the principle of "strict law," so-called, which demands a fixed penalty for every criminal offense and the infliction of that penalty in every case to which it applies; and the other is the principle of the individualization of punishment, which assumes a sufficient discretion to be vested in the court to permit an adjustment of the penalty to the circumstances of the individual case. Beccaria, shocked by the vagaries and partialities of the courts of his day, demanded a criminal law in which every crime should have a fixed penalty unalterable in the discretion of the judge. But, in the exact sense of the term, there has never, in fact, been a regime of strict law strictly enforced. Always there have been loopholes, discretion, warranted or unwarranted, exercised by the judge or the jury or, in the last resort, by the executive head of the state. The nearest approximation to strict law that now obtains is, in England or the United States, the mandatory penalty of death or of life imprisonment for murder and a few other offenses, and even in these cases the rule is more often honored in the breach than the observance. Assuming crime to be sin it is still necessary to look into the heart of the sinner to ascertain the degree of his sinfulness, and this is explicitly recognized in the French *Code pénal*, which permits the jury to find mitigating circumstances (*circonstances atténuantes*) and thereby require the judge to impose a lighter sentence than he might otherwise inflict. In all modern communities today the court is invested with a considerable discretion in most types of cases to determine the penalty to be imposed within wide limits fixed by statute or even to suspend sentence altogether and release the offender on

probation, subject generally to the supervision of an official or agent of the court.

These practices are based on the true principle of individualization, that the crime is not the measure of the man, that among offenders of the same type there may be marked differences of character and personality and that many of them are reformable or, at least, deserve another chance; the same tolerant principle inspired the widespread use of the indeterminate prison sentence, usually only for first offenders, on the further assumption that it should be possible for the prison authorities or an official parole board to determine the date when such a prisoner, having learned his lesson, might safely be released into the outside community under such supervision as an official parole officer might supply. These convictions, swept along on the tide of humanitarianism which characterized the nineteenth century, further manifested themselves in the institution of protectories, or houses of refuge, as they were generally called, for child offenders under the age of sixteen, and of state reformatories for still youthful criminals from sixteen to twenty-five or even thirty years of age whose sentence was almost wholly indeterminate. But the movement whose achievements have thus been recorded did not reach its culmination until the dawn of the present century when, by an act of the Illinois legislature, the juvenile court came into being. Thus, for the first time in the long history of society's unequal warfare against crime, introduced a wholly new note, that of protection rather than punishment for the delinquent of tender years. This it effected through the inspired device of committing every type and case of juvenile delinquency to the more tender mercies of a court exercising not a criminal but a protective jurisdiction, modeled after the chancery courts of England and the United States.

It thus appears that the principle of the individualization of treatment has come in large measure to be the accepted policy of the law in dealing with offenders of all grades, but that it is, as yet, a selective process based on such knowledge of human nature and on such a philosophy of life as the individual judge may happen to be endowed with. It does not carry far enough. It must be reinforced by a new doctrine of sufficient authority to command the appropriate treatment for every offender. Such a new doctrine is emerging in a new conception of the individual based on the clinical psychol-

ogy of the present century. It was not Lombroso but the Viennese physician and phrenologist, Franz Joseph Gall, who at about the beginning of the nineteenth century argued on the basis of his psychological studies that the individual criminal must be studied to be understood and that he must be understood to be wisely dealt with. Lombroso carried Gall's doctrine further — too far, perhaps — and in so doing gave the principle a commanding position in criminological science. It has by now become the conviction of every criminologist worthy of the name and it is rapidly making its way into the consciousness of the great community. The criminal may or may not be a sinner. That may concern the Almighty or it may concern the church, but it does not concern the general community or the law. What does concern citizens and their law is the fact that he has somehow, perhaps as the result of an unfortunate heredity or of the chances of life or for any other reason, disclosed himself as a nuisance or a menace in an orderly society. Manifestly something must be done about him; to know what to do society must know him, and to know him it must get to know how he has come to be the nuisance or the menace that he has proved to be. Law will still be needed, although not perhaps a criminal law, to exercise such restraint as may be necessary. Perhaps as the new wisdom increases it may be found that the equity, or chancery, jurisdiction with which the typical juvenile court is invested will answer the purpose. Or perhaps the psychiatric clinics and the staffs of social investigators with which criminal courts are equipping themselves may in the course of time transform those hoary institutions from courts of criminal justice into courts of social and personal amelioration. Dean Pound has told how Sir Edward Coke, in the dawn of the seventeenth century, bemoaning the savagery of the criminal law and procedure of his time, made an impassioned plea for a preventive instead of a punitive justice and invoked the blessing of God upon him "that layeth the first stone of this building." The first stone is being laid.

CRIMINAL PSYCHOLOGY. See ABNORMAL PSYCHOLOGY.

CRIMINAL STATISTICS. If ideally constituted, criminal statistics would include statistics relating to crimes and criminals collected at all the important stages of criminal procedure. They would begin with the statistics of crimes known to the police, would follow the procedure step by step through arrest, preliminary hearing, grand jury action, the work of the prosecuting attorney and the trial court and would conclude with statistics of probation, imprisonment, parole and action of the pardoning power. They would encompass all minor infractions of the law as well as the serious crimes. Such criminal statistics would be invaluable not only to those interested in the workings of the machinery of government and in the practical results of legislative action but also to those who are seeking to understand the phenomenon of crime itself. The contributions which the various parts of the machinery of criminal justice are making to the work of controlling crime could be estimated. The statistics would also throw much light on the value of any law designed to control or regulate human conduct through resort to criminal procedure. Statistics of crimes known to the police not only indicate the activity of criminals but also reveal, in part at least, the extent of the injury which society has suffered therefrom. Gradually, as the statistical tale unfolded, the outlines of the criminal group would begin to appear. Through proper correlation with population statistics the characteristic features of criminal groups could then be determined and the way prepared for intensive studies of a non-statistical character.

In criminal statistics three different units—the crime, the case and the criminal—are used, depending partly on the particular purpose in

view and partly on the necessities of the given situation. The crime must necessarily be used as the unit in the statistics of crimes known to the police, for at this stage nothing is known about the perpetrators. One individual may commit many crimes or several people may combine to commit a single crime. If the investigator is interested solely in the problem of space in institutions or in the number of cases handled by probation or parole officers, the criminal is the unit used. From the point of view of sociological investigations the two units—the crime and the criminal—must be used in close coordination. The case consisting of one or more crimes and of one or more possible criminals is the important unit when criminal statistics are considered as an instrument for measuring the efficiency of police and court activity.

Criminal statistics relate to a period of time and not to a point of time. Furthermore, a crime known to the police one year may have been committed by a criminal caught and convicted the next year whose final release from prison may not take place for many years to come. Since many offenders are caught soon after their crimes and sentenced for short terms, they and their crimes may appear more than once in the statistical tables of a single year. These statistical difficulties are not always recognized in the compilation and analysis of the figures and lead to false conclusions.

No nation possesses well rounded and well organized criminal statistics. Those of England and Wales approach the ideal more closely than do the statistics of any other nation. They cover the entire range from the statistics of crimes known to the police to prison statistics. Police statistics are as a rule less developed than any other branch. The collection of statistics relating to convictions in courts of record has received most attention in Europe. In the United States only prison statistics and a few police statistics have been collected by the federal government. The collection and the compilation of criminal statistics are in the several countries carried on by different bureaus or departments. In France, Germany, Belgium, Austria and Italy the work is located in the departments of justice, which have broad administrative powers. In England the Home Office carries on the work. In the United States the Bureau of the Census in the Department of Commerce handles the prison statistics and the police statistics are compiled in the Department of Justice. The criminal statistics of Canada, Australia and New Zealand

are collected and compiled by general statistical bureaux unrelated to departments of justice and corresponding somewhat to the Bureau of the Census in the United States.

International comparisons of the results of criminal statistics are fraught with great difficulties. The legal and administrative setting varies with the country. Crimes of the same name are defined differently; acts which are crimes in one country are not crimes in another. Prohibition and its train of consequences illustrate the difficulty of any comparison of United States criminal statistics with those of a country which merely restricts the sale of intoxicating liquors. Efforts have been made in vain to work out an international classification of the important crimes.

The collection of criminal statistics in the United States is still in the embryonic stage. Reformatories, juvenile courts, indeterminate sentences, parole, probation, psychiatric and psychological examinations develop and ramify, but almost nothing is known officially about the results of these various innovations, and the crime rate seemingly remains high. The dearth of statistical information may be ascribed to the fact that in the making of laws relating to crime and criminals each state is supreme within the limits imposed by the federal constitution. Uniformity of culture is sufficient to insure that the essential features of criminal justice are similar in all of the states, but differences in matters of detail create genuine obstacles to the collection of criminal statistics. A crime in one state may not be a crime in another, and the punishment decreed for a given crime in one state may be greater or less elsewhere. Differences in details of court organization and procedure render difficult the collection and analysis of comparable statistical data. Police departments are organized and run on diverse plans, and penal systems vary from state to state. Other reasons for the existing situation with respect to criminal statistics are the spoils system of governmental administration, the opposition of law enforcement agencies whose ineffectiveness might be exposed and the general indifference, broken only by spasmodic severity, which has characterized the national attitude toward crime.

The first collection of criminal statistics in the United States was made in 1829, when the clerks of courts of record in the state of New York were asked to send the secretary of state a record of the convictions obtained in their respective courts. The purpose of collecting these

data was to make available the evidence of former convictions in dealing with offenders suspected of being recidivists. In 1838 the senate asked the secretary of state for an abstract of these records, and his report, covering the years 1830 to 1837 inclusive, did not relate solely to recidivism but analyzed the materials carefully. Massachusetts since 1832 has required the attorney general to present a report to the legislature on the suits and prosecutions which he attended together with an abstract of reports made to him by local district attorneys. A number of other states now require similar reports. The purpose behind such legislation is not the scientific collection of criminal statistics but the desire to keep an account of the activities of the attorney general, the prosecuting attorneys and the more important courts. These data have for the most part been badly collected and except in Massachusetts have been of little or no value. Many states make efforts to supervise their penal and correctional institutions and provide fiscal and legislative control by calling for statistics from sheriffs, wardens and keepers. These are usually of poor quality.

The federal government began in a tentative way to collect statistics relating to criminals in connection with the census of 1850 by means of both the general population schedule and the schedule for social statistics. The results were fragmentary and useless, owing to the haphazard method of collection through assistant marshals. The inquiries of 1860 and 1870 were likewise of little value. These collections of criminal statistics had unfortunately been combined with the decennial population census. In enumerating the population the object is to discover how many people are in the country at a given point of time. Even in 1850 this was not considered the proper procedure for the collection of criminal statistics, and the Bureau of the Census attempted to count as convicts not only those who were in prison but also those who, although released, had been convicted of crime within the year. The assistant marshals were asked to get this information from court records, but there was no machinery for that purpose and the effort failed. Frederick H. Wines, who was appointed in 1880 to direct the division of social statistics relating to pauperism and crime, also recognized that mere enumeration of the prison population was inadequate and sought to obtain additional information from court dockets, justices' returns and police reports. The figures which he collected and analyzed, however, re-

lated largely to the individuals found in prison on the day of the enumeration. In 1904 the Bureau of the Census under the direction of John Koren made a special inquiry, dissociated from the general enumeration of the population, which emphasized the collection of figures for crimes committed during that calendar year. This procedure was also followed in the investigations of 1910 and 1923. The Bureau of the Census tried again in 1907 to collect data on crimes and criminals from court records, but the attempt met with complete failure. The bureau has made no further efforts in this direction but since 1926 has undertaken to obtain statistics annually from state and federal prisons and reformatories, omitting the figures for county and city penal institutions compiled in the decennial enumerations. Statistics derived from prison records alone are, however, obviously insufficient and may be very misleading. For example, no probationers are represented by prison figures and those who pay fines are not included. Until the federal government can obtain data from court records, many of the most important facts with regard to crimes and criminals will escape collection.

Discontent with the machinery of criminal justice has led to investigations which have thrown additional light on the problems of collecting statistics from court records. In certain states and cities (Missouri, Illinois, Pennsylvania, New York, Cleveland) determined efforts have been made within the last few years by means of crime surveys or commissions to measure the work of the courts and the police by the statistical method. Temporary organizations were developed to ascertain the number of arrests made, the number of cases heard by justices of the peace or police magistrates, the number thrown out by public prosecutors and by grand juries, the number tried and the number of individuals sentenced, placed on probation, fined or sent to prison. In all cases these statistics had not been previously available. The life of the commissions was limited and their reports, while invaluable in portraying the workings of the machinery of criminal justice, had no permanent results as to practices of compiling criminal statistics where new state machinery was not created to carry on their work.

Progress has recently been made in the field of police statistics. At the 1927 convention of the International Association of Chiefs of Police a Committee on Uniform Crime Records was appointed. Under the direction of Bruce Smith

with the assistance of the Detroit Bureau of Governmental Research a comprehensive investigation was made, including a study of police records and the diverse systems of criminal law in the forty-eight states. The committee first published a tentative guide for preparing annual police reports and a tentative uniform classification of major offenses. In 1929 the committee published a volume on *Uniform Crime Reporting*, which deals primarily with the fundamentals of police statistics and is also a contribution to the science of criminal statistics. Its system of uniform classification of offenses, based, with some changes, upon that employed by the Bureau of the Census, has already been widely adopted. The committee issued in January, 1930, its first monthly bulletin of offenses known to the police covering an area with a population in excess of twenty millions. An act authorizing the National Division of Identification and Information of the Bureau of Investigation of the United States Department of Justice to collect and compile crime statistics was approved the following June, and beginning in September this bureau assumed the work of the Committee on Uniform Crime Records and has since published monthly bulletins. This promising development is hampered by the fact that the contributions of the police departments to the Bureau of Investigation are entirely voluntary, and while the size of the registration area more than doubled in eight months many important regions have as yet made no returns. Moreover, the reporting is limited to seven classes of grave offenses: felonious homicides, rape, robbery, aggravated assault, burglary, larceny and automobile theft. The fact that police departments had already cooperated with the Bureau of Investigation in recording fingerprints determined the decision to place this statistical work in that bureau instead of in the Bureau of the Census. It is suggested that the state bureaus of identification, now twenty-four in number, should take up the work of collecting criminal statistics. A plan is needed for the collection of court statistics similar in scope to the plan for police statistics worked out by the Committee on Uniform Crime Records. State bureaus need scientific direction, for without it systems differing in essential details and unsuitable as the basis of a unified system for the whole country will develop.

CRIMINAL SYNDICALISM is a legal concept which owes its origin to the growth of syndicalist and other revolutionary labor movements in the United States. The concept is embodied in a series of state laws known as criminal syndicalism laws, the essence of which is the prohibition of doctrines and activities involving the use of violence as a means to social change.

For a number of years immediately preceding the World War the activities of the Industrial Workers of the World among the miners, lumber workers and agricultural workers of the western and northwestern states had aroused the fears of employers and of the middle class and had resulted in attempts by local authorities to stamp out the organization. The coming of the World War added the fear that the I. W. W. would obstruct the war activities of the government as it allegedly had in other countries, especially Australia, where the government in 1916 had found it advisable to pass an Unlawful Associations Act making membership in the I. W. W. a criminal offense punishable by six months' imprisonment.

The first criminal syndicalism law in the United States was enacted in the state of Idaho in 1917. It defined criminal syndicalism as "the doctrine which advocates crime, sabotage, violence, or other unlawful methods of terrorism as a means of accomplishing industrial or political reform." The law declared that "the advocacy of such a doctrine, whether by word of mouth or writing, is a felony" and set the maximum penalty at imprisonment for ten years or a fine of \$5000 or both. Minnesota followed in the same year and five other states in 1918. Most of the criminal syndicalism laws, however, were passed during 1919 and 1920, inspired not by the necessity of safeguarding war activities but by the fear of revolution aroused by the post-war social upheavals, especially in Russia.

As a result of the legislation from 1917 to 1920 there are at the present time twenty-one states and two territories which have laws covering criminal syndicalism. In sixteen of the states the acts are worded almost exactly like the Idaho law of 1917. Arizona and North Dakota do not mention the words "criminal syndicalism" but cover the same activities under the word "sabotage," while Kentucky and West Virginia mention neither term in their general sedition laws, which cover the same field. Sabotage is defined in some statutes, such as that of Minnesota, as "malicious damage or injury to the property of an employer by an employee." The penalties usually provided in the laws are imprisonment from one to ten years or a fine of from \$1000 to \$5000 or both. The highest penalty is in the state of South Dakota, which provides a maximum penalty of twenty-five years' imprisonment or a fine of \$10,000 or both. State supreme courts, when called upon to pass on the constitutionality of the laws, have

uniformly upheld them, with the exception of Montana, where the law was declared void on the technical ground that its title was defective.

The enforcement of the criminal syndicalism laws has given rise to important issues of law and public policy, involving the conflicting problems of freedom of speech and public safety and the methods which may be employed for securing political and social reform. The trend of the decisions has been to hold that mere membership in an organization formed to advocate violence for effecting any economic, social or political change is sufficient basis for conviction. In the case of *Fiske v. Kansas* [274 U. S. 380 (1927)] the Supreme Court of the United States held that it was necessary to prove that the organization actually advocated "crime, violence, or other unlawful act as a means of effecting industrial or political change." For this purpose a mere reading of the preamble of the constitution of the I. W. W. was insufficient, and the conviction of *Fiske*, based only on that evidence, was reversed as violating the due process of law clause in the federal constitution. The same day the Supreme Court handed down a decision in the *Whitney* case [274 U. S. 357 (1927)], which had attracted nation wide attention. Miss Charlotte Anita Whitney, a Wellesley graduate active in philanthropic work, had been arrested and convicted under the California criminal syndicalism law on the basis of her membership in the revolutionary Communist Labor party. At her trial a considerable part of the evidence against her consisted of citations of activities of the I. W. W. with which she had never been connected but which had been endorsed by the Communist Labor party. Her conviction was sustained by the Supreme Court on the ground that although she herself favored only peaceful political methods she had continued as a member of the California branch of the Communist Labor party after that party had adopted a platform advocating social revolution and endorsing the activities of the I. W. W. In rendering the decision Mr. Justice Sanford emphasized that the act could not be held invalid on the ground that it restricted the rights of free speech, assembly and association because the constitution does not confer the right of unrestricted use of language; that conspiring with others in an association for the accomplishment of desired ends through the advocacy and use of criminal and unlawful methods partakes of the nature of criminal conspiracy; and that, as such association involves greater danger to the public

peace and security than the isolated utterances and acts of individuals, it is not an unreasonable exercise of the police power of the state to prohibit such associations. Mr. Justice Brandeis and Mr. Justice Holmes, while concurring in the decision on the ground of the court's limited power of review, took the occasion to restate the doctrine that, while the right of free speech is not absolute, a definite test for restricting it should be applied—the test of "clear and present danger," which had been applied by Mr. Justice Holmes in a previous decision under the Espionage Act [*Schenck v. U. S.*, 249 U. S. 47 (1918)].

From 1919 to 1924 prosecution under the criminal syndicalism laws was fairly active in various states, especially in California. In that state 531 individuals were indicted under the law between the years indicated. Of these 264 were actually tried, 164 convicted and 128 sentenced for terms ranging from one to fourteen years. In the California trials the same prosecution witnesses, especially two former I. W. W. members, appeared time after time. Defense witnesses who admitted membership in the organization while on the witness stand were in many cases arrested on leaving the courtroom and convicted under the criminal syndicalism law. A peculiar feature of the administration of the law in California was a state wide injunction, issued by Judge Charles O. Busick in 1923 and upheld by the Supreme Court of the state [*in re Wood*, 194 Cal. 49 (1924)], which enjoined the very acts classed as crimes under the law. I. W. W. offenders were thus removed from the control of juries, which sometimes showed reluctance to convict, to that of the judge, who could sentence them for contempt of court. In California as in other states practically all prosecutions were directed against members of the I. W. W., although a few cases involved members of the Communist Labor party, organized in 1919.

It is impossible to say whether these prosecutions and indictments had the desired effect. There is no doubt that the I. W. W. and the Communist organizations declined after 1921. But other labor organizations which were not affected by the criminal syndicalism laws also suffered losses in membership and strength. The radical and revolutionary movements in America during the last few years have been adversely affected by general economic and political conditions and would probably have declined even if no special law had been passed against them.

Many of the sentences under the criminal syndicalism laws have been reversed by higher state courts. In other cases the executive authorities have pardoned those convicted under the laws; Miss Whitney was pardoned by Governor Young of California shortly after the Supreme Court's decision in her case, and the last of the California prisoners were released in 1928. By January, 1929, there were no persons in the United States in prison under the criminal syndicalism laws. This would indicate that in times of social calm such laws tend to become a dead letter. As long as they remain on the statute books, however, they represent a potential weapon which may be used again under conditions of social stress. Thus the Ohio criminal syndicalism law was revived and employed successfully against two Communist propagandists in 1930.

W. W.: a Study in American Syndicalism* (2nd ed. New York 1920).

CRIMINOLOGY deals particularly with the criminal himself, giving special emphasis to the problem of the causation of crime. Scientific interest in the study of the criminal came late because the criminal was classed with the sinner as a theological problem. Both were considered perverse free moral agents who had deliberately violated the will of God. The criminal had also defied the law of the land, and savage punishment was therefore believed to be thoroughly deserved. The full responsibility of the criminal for his own conduct was assumed, and the persons who prescribed and executed punishment were believed to be serving God as well as man. Hence there was little basis for restraint in punishment or little incentive to look into the problem from a naturalistic or human point of view. The rise of scientific criminology had to wait upon the development of a new intellectual

perspective and the accumulation of scientific knowledge which would undermine the ancient theological approach to the criminal and his treatment. Criminology is therefore distinctly a product of the nineteenth century although its foundations run back into the first half of the eighteenth.

The origins of a scientific interest in the nature of the criminal were derived from biology and physiology. Aristotle in his treatise on physiognomy anticipated the criminal anthropologists to some extent, and by the time of Grataroli and Della Porta physiognomics had reached a fairly high state of development. With Lavater (1741-1801) and Gall (1758-1828) scientific criminology begins. There is a real filiation of doctrine running through the physiognomists to Gall, Morel and Lombroso. These men drew upon the early physical anthropologists and physiologists and tried as far as possible to use scientific methods in clearing up the mysteries of human behavior. To this group rather than to the criminal law reformers must be assigned the credit for establishing scientific criminology.

Another impetus to criminology and the improved treatment of the criminal was derived from criminal jurisprudence, which strove to abolish torture and to eliminate the barbarous punishments that characterized European procedure. Montesquieu in his *Lettres persanes* (1721) in the form of satire and irony ridiculed the prevalent barbarism in the treatment of criminals. The abuses also attracted the stinging criticism of Voltaire. But the most influential work of the eighteenth century was that of Cesare Bonesana, Marchese di Beccaria. Beccaria's essential doctrines were: the criterion for all reform must be the greatest happiness for the greatest number; the seriousness of a crime must be measured by its injury to society; prevention of crime is more important than the punishment of crime; punishment is to be justified through its power to deter from crime and not as social revenge; torture must be abolished and a fair trial insured; more use should be made of imprisonment in the place of corporal punishment as the mode of handling criminals. To Beccaria's work may be traced, in part at least, the reform of the criminal law of Austria, the penal code of the French Revolution, the reforms of Romilly and Bentham in England and the transformation of the criminal law in the United States following the Revolutionary War.

The leader in the reform of the criminal law in

England was Jeremy Bentham (1748-1832). Bentham applied the principles of his felicific calculus to the reform of the criminal law and proposed that penalties be moderated and that the penalty for each crime be so fixed that the pain imposed would be sufficiently in excess of the pleasure derived from its commission to deter men from committing crime. He recommended a greater use of imprisonment as a means of punishment and outlined an ideal prison structure—the Panopticon and a rational system of prison discipline. Samuel Romilly (1757-1818) led in the practical reform of the brutal criminal code of England, aided by James Mackintosh, Thomas Foxwell Buxton and Robert Peel. In 1800 there had been more than two hundred capital crimes; by 1861 there were but three: murder, treason and piracy. The early prison reformers John Howard (1726-89) and Elizabeth Fry (1780-1845) also directed attention to the personality and special treatment of the criminal. The humanizing of the criminal code in the United States was due to the Pennsylvania Quakers who, shocked at the bloody scenes attending the corporal punishments of the period, worked for legislation which would substitute imprisonment for corporal punishment. They were aided by William Bradford, who attacked the savage criminal codes of colonial days and drafted the revised codes of Pennsylvania, which by 1794 had substituted imprisonment for corporal punishment and made murder in the first degree the only capital crime.

The originators of modern criminology are Cesare Lombroso (1836-1909), Enrico Ferri (1856-1928) and Raffaele Garofalo, who together are designated as the Italian school. Lombroso's work became the point of departure for the science. Lombroso was early convinced that the criminal constituted an unmistakable abnormal type, distinguishable by characteristic stigmata, anatomic, physiological, psychological and social. His theories grew in comprehensiveness and acumen as he became older and more experienced in his investigations. His first theory was that the criminal type was explainable by the principle of atavism, or reversion to a more primitive type of the species. Lombroso attempted to prove his theory of atavism by a comparison of the anatomical and organic characteristics of the criminal and primitive man and by showing that the actions of the savage were normally criminal. The first of these proofs is not difficult, if one accepts the doctrine of

analogy as sufficient for scientific purposes and admits Lombroso's description of the criminal. To demonstrate the normal delinquency of the savage is, on the other hand, an impossibility. Lombroso soon saw the incompleteness of the theory of atavism and introduced the theory of Esquirol, Pritchard, Despine and Maudsley that many of the criminals were to be accounted for on the basis of moral insanity. Not satisfied with this he finally advanced the third theory that at least all born criminals could be accounted for on the basis of being epileptics. But Lombroso never abandoned his main theory of atavism. He regarded moral insanity and epilepsy as simply secondary manifestations of atavistic characteristics.

Lombroso recognized other classes and gradations of criminal besides the typical born criminal with which his above theories are mainly concerned. He carried out with considerable completeness a detailed classification which included criminals by passion, linked with a subdivision of political criminals accentuated by excessive patriotism; insane criminals, further divided into alcoholic criminals, hysterical criminals and the criminal matroid; occasional criminals, with subclasses of pseudo-criminals, criminaloids and those who are normal organically but have drifted into crime through lack of or failures in education or from evil associations primarily caused by a defective social environment. Lombroso was therefore not so narrow as some of his critics, who claim that he recognized only the born criminal, would try to show. His great contribution to criminology was his general point of view, not his specific doctrines. His doctrine of a born criminal and his dogma that the criminal can be detected by definite physical stigmata are no longer taken seriously. The physical stigmata he enumerated are found in connection with degeneracy and feeble-mindedness generally, while there are a large number of criminals of high intelligence and excellent physique. Moreover, there are numbers of law abiding citizens who possess many of his criminal stigmata. But by taking the discussion of crime out of the realm of theology and metaphysics and putting it on the positivistic basis of a consideration of the characteristics of the criminal, he may be said to have founded modern criminology.

Lombroso was followed by Enrico Ferri, who presented a comprehensive theory of criminal factors and a widely adopted classification of criminals. He conceived of the penal function in

terms of the social body defending itself and sought to replace and transform criminal jurisprudence by sociologic science. The factors of crime he classified as individual or anthropological, physical or natural, and social; the anthropological factors comprising age, sex, civil status, profession, domicile, social rank, instruction, education and the organic and psychic constitution; the physical factors including race, climate, the fertility and disposition of the soil, the relative length of day and night, the seasons, meteoric conditions, temperature; and the social factors covering the density of population, emigration, public opinion, customs and religion, public order, economic and industrial conditions, agriculture and industrial production, public administration of public safety, public instruction and education, public beneficence and in general civil and penal legislation. Ferri's classification of criminals differentiated between the habitual and the occasional criminal and finally included five classes: born criminals, criminal lunatics, habitual criminals, occasional criminals and emotional criminals. Ferri sounded the keynote of modern penology when he demonstrated that the function of penal institutions and criminal jurisprudence is to defend society from parasitical organisms. In addition he proposed an elaborate series of what he called penal substitutes which, preventive in their nature and designed to do away with crime, avoid the necessity of punishment.

Garofalo's theories were founded on the distinction between the *jus naturae*, on the one hand, and the *jus gentium* and *jus civilis*, on the other, and revolved around his fundamental doctrine of the "natural crime." Natural crimes he defined as crimes against the law of nature—i.e. the rules of right conduct revealed to man through his reason—and he interpreted offenses "that have been considered punishable at all times and in all places" as offenses "against the fundamental altruistic sentiments of pity and probity in the average measure possessed by a given social group." Crimes other than those which make up the natural crimes were those which constitute a violation of positive (man made) laws, which do not comprise a codification of the principles of natural law. He believed that both types must be punished but that the main interest of the criminologist should be in natural crimes. Garofalo's classification of criminals was based largely upon the nature of their crimes: namely murderers (offenders against humanity), thieves (offenders against

property), cynics (sexual criminals) and violent criminals. He described the first three classes as morally color blind and the violent criminal as totally blind morally. All classes were to be explained upon the basis of moral anomaly or ethical degeneration. Garofalo denied that there had been conclusive demonstration of a criminal type distinguishable by anatomical abnormalities, but he asserted that all true criminals as abnormal types had an inherent tendency toward crime and that no normal man committed a natural crime through the influence of the environment alone. Garofalo advocated a great extension of the application of the death penalty, contending that society must accomplish by artificial means what nature does in the biological world, by eliminating those criminals who would not be adjustable to any physical or social environment. All those in whom there is a considerable lack of pity and probity, although not enough to warrant their execution, were to be expelled from free society. Garofalo defended the principle that reparation for damages be made by all those criminals whose abnormality was not sufficient to justify their elimination.

The points of agreement in the theories of the pioneers of criminology are that the criminal is not a normal person who commits crime simply from perversity; that the true criminal is an abnormal type; and that his offense is the result of manifold influences operating upon an abnormal personality. They established the fact that the criminals are of different grades, gradually shading off into normal individuals. They held that those classes which are distinguishable by organic differences and distinct offenses must be differentiated in the process of treatment as well as for purposes of study. Finally, they introduced the new idea of social defense in the methods of penology, thus abandoning the old idea of purely retributive justice.

There are three main types of theories or schools in recent criminology: the first, which stresses the anthropological influences, the anthropological school; the second, which emphasizes the social forces working upon crime, the sociological school; and the third, a group which can hardly be called a school, which lays particular stress upon the influence of the physical environment, such as climate and weather. The anthropological theories deal especially with the alleged individual characteristics of the criminal classes and hold that the environment, especially the social environment, is less important as a factor in criminality than the per-

sonality of the criminal. While most criminal anthropologists have laid emphasis upon the assumed anatomical characteristics of the criminal, some have disregarded these and have given the most attention to the psychic traits conducive to criminality.

Of all the anthropological theories the most spectacular has been that of atavism, which traces its development in its modern connotation from the works of Lombroso. Contemporary with Lombroso a Frenchman, Bordier (1841-1910), also formulated a rudimentary theory of criminal atavism from a comparison of the skulls of murderers with those of prehistoric men; and an Austrian psychiatrist, Benedikt (1835-1920), who examined the brains of beheaded criminals, reached the conclusion that their brains showed a departure from the normal which approximated the brains of the quadrupeds and that therefore the criminal exhibited an inferior cerebral equipment which made his adaptation to the social environment impossible. Colajanni (1847-1921) rejected all claims for evidence of anatomical reversion and maintained that the atavism which explained criminality was to be looked for in the moral realm, where the criminal exhibited the rudimentary morality of the savage. Extensive researches in the field of primitive culture and of mental testing have revealed the erroneous nature of these theories. More recent adherents of the atavistic theory have revised the cruder statements of the earlier leaders. Ferrero asserts that the main truth in the theory of atavism is the possession by the criminal of certain psychic characteristics common to primitive man, the most important of which are laziness, impulsiveness and physio-psychic excitability which makes them unable to adapt themselves to the uniformity and regularity of civilization. Closely allied with atavism is the theory of arrested development of the criminal as advanced by Havelock Ellis, which is based upon the theory that the life history of the individual offers a recapitulation of the development of the species.

After atavism the most famous anthropological explanation of crime is that of degeneration, or retrograde evolution. The origins of this view must be attributed to Franz Josef Gall (1758-1828), the father of phrenology and physiological psychology, whose doctrine was based on the theory of the localization of brain functions and who held that crime was due to the degenerative effects of the hyperfunctioning of certain brain centers. Morel in 1857 advanced a

theory of degeneration to account for the criminal on the basis of retrogressive natural selection, and Despine in 1868 described the criminal as a moral anomaly. There are few if any adherents to the theory of degeneration who would claim the absolute identity of degenerates and criminals, but all maintain that a close relationship exists between the two types. The Frenchmen Magnan, Féré, Corre, de Montyel and Dallemange established the foundations of this general relation between degeneracy and criminality. In addition the Italian Marro after patient microscopic investigation presented the theory that crime may be traced to the defective nutrition of the central nervous system, which leads to an imperfect functioning of the directing and controlling force in the human mechanism. The Italian Bonfigli and the Russian Kovalevsky (1840-1901) attributed crime to the defective development of the inhibitory centers of the brain. The theory of moral insanity, which had its origin with Esquirol, Pritchard, Despine and Maudsley (1835-1918) and has had many English adherents including Francis Galton, attempts to correlate degeneration and crime. Ribot, Bleuler and Virgilio have all supported this theory. Nücke and Bernaldo de Quirós have criticized it on the ground that moral insanity does not usually go with a sound intellect. The epileptic nature of the criminal has been extensively dwelt upon and has received its main support from the Italians Roncoroni, Ottolenghi, Tommini, Cividalli and Capano and from the Englishman Lewis. Just as epilepsy is the typical pathological clue of the Italians, neurasthenia as an explanation of the criminal claims most of its support from the German speaking authorities, chiefly the Austrians Benedikt and Vargha and the German Liszt. Some writers have seen the difficulty and danger involved in attempting to reduce the various pathological bases of crime to that of a single pathological characteristic and have indicated the many factors that are involved in typical criminality. Of these analytical writers the most distinguished is the Argentinean Ingenieros, who in 1907 classified the psychopathic states related to criminality under the headings of intellectual, volitional and moral anomalies and discussed the relative influence of individual and external factors among the different types of criminals. From the multiplicity of anthropological theories two main conclusions may be drawn: that it is impossible to reduce the many physio-psychic factors to a single explanation of criminality and that a multiplicity of

abnormalities are found among the typical criminal class, although all are rarely if ever combined in a single individual. The contribution of criminal anthropology has been to distinguish between typical and occasional criminals and to argue for the fact that the former is an abnormal being, marked off from the rest of society as much by personal defects as by the deviation of his actions from the accepted forms of conduct.

Criminal sociology emphasizes the external factors in the production of crime which are supplied by the social environment. Sociological theories vary all the way from those which represent a combination of the anthropological and sociological factors to those which regard the anthropological elements as either negligible or simply the resultant of social causes. Of the exponents of the socio-psychological theories the most eminent has been Gabriel Tarde. Tarde's general doctrine of the paramount importance of the social environment has been applied in many special social theories. Émile Durkheim held that crime is a natural and inevitable incident of social evolution, that a minimum amount of individual freedom is necessary for social development and that a fringe of society is bound to take advantage of this freedom and flexibility to commit crime. He held that any society sufficiently repressive to cut off all crime would produce such a degree of social and cultural rigidity that there could be no progress and that therefore a certain price must be paid for the evolution of our culture and institutions. The anthropo-sociologic theories of criminology of the Frenchmen Lacassagne, Dubuisson and Aubry did not deny the influence of the anthropological factors in producing crime but claimed that they are of little importance if considered apart from social surroundings—the sanest of all views. The Italian Vaccaro contended that criminality was the result of the lack of adaptation of the individual to the social environment. His theory is based upon the principle of the struggle for existence, and he maintained that those who are left behind in this struggle are likely to become criminals from exhaustion and degeneration and from their tendency to rebel against those who have outdistanced them in the strife for supremacy. Crime appears to Vaccaro as an act which the winners in the struggle, who constitute the ruling power, consider dangerous to their interests; the criminal appears to him as a rebel against the complicated system by which the winners try to

develop only the aptitudes which they can better utilize for their ends. The theory of the psychic segregation of the criminal as advanced by the Frenchman Aubert ascribes to the criminal an exhausted nervous system, through which he becomes subject to the feeling of a frustrated life and a fear of poverty and ignominy leading to a differentiation from the human center and producing a life of organized hostility to it known as crime. An ingenious theory concerning the social factors in criminality is that of the social and economic parasitism of the criminal put forward by the Spaniard Salillas (1855-1923) and developed by Max Nordau. They held the criminal, especially the habitual criminal, to be one who is out of adjustment with his social environment and who readjusts himself to it in the abnormal manner which constitutes crime. Socialist writers attribute crime to the exploitation of the laboring class, which leads to poverty and incomplete development. They consider the present system of penal justice to be one designed to protect the interests of the usurping capitalistic class and contend that if socialistic reforms are effected the causal conditions of crime will be removed and delinquency will tend to disappear. This socialistic school has been mainly supported by a group of Italian writers, the most important of which are Turati, Colajanni and Loria. Ferri, who at first was an opponent of the socialistic theory, became more and more attracted by it and in 1894 declared his conversion. The main contribution of Ferri is his attempt at synthesis and the resultant theory that socialism and criminal anthropology and sociology supplement each other and harmonize thoroughly. Bonger, the Dutch criminologist, is also an advocate of the socialist interpretation of the cause of crime.

A group of writers have considered the immediate relation between criminality and varying conditions of the physical environment. The pioneer exponent of this doctrine was Montesquieu, who derived many of his ideas on climate and legislation from an English writer, John Arbuthnot. Montesquieu laid down a law, which is pure conjecture, that criminality increases in proportion as one approaches the equator and drunkenness as one approaches the poles. About a century later Quételet put forward his "thermic law of delinquency," that crimes against persons were prevalent in the south and crimes against property in the north. Ferri called attention to the influence of the physico-environmental factors influencing criminality

The American statistician Mayo-Smith maintained that later investigations had tended to confirm Quételet's law and that crimes against property were most numerous in winter and those against persons in summer. Dexter more recently has studied the direct influence of meteorological conditions such as barometric pressure, heat, humidity and air currents upon the commission of crime and has reached the general conclusion that the percentage of crimes committed declines in direct proportion to an increase in heat and humidity and a decrease of barometric pressure. While all writers in this field recognize that these meteorological conditions alone cannot make a criminal, they hold that these factors exert a considerable influence upon the occasional and habitual criminal and may determine to a certain extent the time of their outbreaks of criminality.

The character of criminology varies in different countries. In Italy, the parent country of criminology, divergent theories of criminology prevail; but the majority of the Italian criminologists are numbered among the anthropological school and the socialistic branch of the sociological school. France probably ranks next to Italy in the extent of the development of the older criminology. Its writers are numbered chiefly among the sociological school, with Tarde occupying the same preeminent place among French scholars that Ferri occupies among the Italians. In Germany the study of criminology has been pursued with scientific exactness. The doctrines of Lombroso were presented to the Germans by Kurella, who translated his works into German and who has been the persistent defender of Lombrosian theories in that country. These ideas have also received more qualified support from Sommer and from Bleuler. The general trend of thought in Germany upon this subject has, however, been decidedly anti-Lombrosian, although biological theories of crime have been popular. Lombroso's main opponents have been Kirm, Baer, Koch, Nacke and Aschaffenburg. In Spain much able work has been done. Among the most important critical criminologists are Montero, Aramburu and Bernaldo de Quirós, the latter being probably the greatest of modern critics. The leader of constructive Spanish criminology was Rafael Salillas, the head of the official school of criminology of Spain. In England Mercier (1852-1919) was particularly active in studying the relation between insanity and criminality. In Austria Bleuler, Benedikt, Gross, Vargha

and Gumpłowicz are best known. Holland has three very able scholars in van Hamel, Bongers and Winkler. Denmark has in Geill a capable opponent of the doctrines of Lombroso, while Switzerland manifests its interest in the crime problem in Stoops' *Zeitschrift für Strafrecht und Revue pénale suisse*. Prius (1845-1919) has done notable work in Belgium. In the United States the development of criminology has been slow but is rapidly gaining ground. Both MacDonald and Drahms, the first scholarly contributors to criminology in the United States, were conservative and critical followers of Lombroso. Frederick Wines (1838-1912), Parmelee and Masten summarized existing criminal theory and McKim urged the extermination of degenerate and habitually criminal types. Advances in the application of psychiatry, mental testing and the sociological approach to the criminal have recently put the United States among the foremost in the science of criminology. In the Argentine Republic the most noted writers on criminology are Ingenieros, Drago, Piñero, Megia, DeVeyga and Arreguine, and the organ of criminology is the *Revista de criminología, psiquiatría y medicina legal*. In Mexico Macedo, Guerrero, Roumagnac and Vergara have been authors of important works on criminology. Latin American criminology work has reacted upon the criminal codes, which in Chile and Mexico embody the principles of modern criminology and stand far in advance of the criminal practise and penal methods of the United States.

Down to the second decade of the present century criminology was chiefly dogmatic and theoretical. It rested more upon generalized doctrines than upon a careful study of individual criminals by scientific methods. It was still chiefly absorbed in the discussions and controversies created by the classical Italian school and their followers and critics. Europe is in fact still greatly influenced by Lombroso and the biological school. The work of Adolph Lenz may be regarded as an effort to bring Lombroso up to date and give the biological school a new vogue. But in the active scientific criminology of today the doctrines of the classical school and of criminologists prior to 1910 have little more than historical import. The deathblow to the Lombrosian dogma of a definitely hereditary type of criminal and of a complete biological interpretation of criminality was given by Charles Goring after extensive observation of numerous types of prisoners. But the epoch making work was

the product of a psychiatrist and criminologist, William Healy, which marks as great an achievement in the second stage of the development of criminology as Lombroso's did in the first. It was Lombroso's great contribution to indicate that the criminal must be studied by scientific methods. Healy was the first to do so in a comprehensive and satisfactory manner by using the psychiatric method and analyzing and defending his methods. He made it clear that dogmatizing about the criminal as a unified type or a collection of arbitrary classes must cease, that the criminal must be studied and dealt with as an individual and that he can never be reformed until treated as such. Healy's work established the case study and psychiatric methods in criminology. The effort of the biological determinists to capture the psychiatric school, through maintaining that although crime must be interpreted in terms of mental diseases the latter are definitely hereditary, was definitely repelled by Abraham Myerson, who proved the slight degree of specific hereditary taint in any major form of mental disorder. Twenty years ago H. H. Goddard popularized the view that the greater part of criminality could be traced directly to mental defects. But the army mental tests proved conclusively that the intelligence of the convicts in the country matched that of the general population as tested in the army sample of 1917-18. Carl Murchison, W. T. Root and others have carried on extensive studies of convict intelligence and have proved that feeble-mindedness is no more marked among convicts than among non-convicts. A new effort to revive the biological interpretation of crime has very recently appeared, due to the influence of the science of endocrinology. In the works of such writers as Pende, Vidoni, Papillault, Mariano Ruiz-Funes and M. G. Schlapp crime is interpreted as the product of endocrine deficiencies, excesses and disturbances. Doubtless this school has a very important contribution to make, but the exclusive biochemical theory of crime must be relinquished and its findings fused in a broad psychiatric conception of delinquency. Since the World War there has been a notable development of criminological laboratories. The labors of Vervaeck in Belgium and Viernstein in Bavaria have been outstanding in this field. Of great interest also have been the recent Russian innovations in the scientific study of the criminal and in radical experimentation with new and more liberal methods of prison administration. Criminological institutes

have been established in connection with prisons in various parts of the Soviet Union, which function as experimental clinics. The largest is the Moscow institute, which is organized into four divisions: the socio-economic, the biopsychological, the crimino-political and the criminalistic. These institutes, manned by specialists, study crime causation and penal methods and formulate practical preventive programs and research methods in studying and treating prisoners. Indeed, these developments together with the new empirical criminology in America constitute the chief dynamic factors in criminology today.

Criminal law and criminal practise are still overwhelmingly dominated by prescientific views of crime and punishment, yet criminology has not been without some influence. There have been some concessions to psychiatry. Massachusetts in 1921 passed the Briggs law, which ordered a mental examination of prisoners held for trial and of convicted prisoners, and by 1928 Overholser discovered that about half of the courts of the United States make some, if only minor, use of psychiatry or medical psychology in their court procedure and disposition of the criminal. It is in the juvenile courts that the chief advances have been made. In such a court as that of Judge Cabot in Boston, maintained by the Judge Baker Foundation, the procedure is in accord with the most rigorous criminal science; psychiatrists and social workers investigate each case and determine its disposition. Criminology has had some influence on the methods of classifying prisoners in courts and prisons; the state of New Jersey, for example, now bases its penal policy and discipline on a scientific classification of convicts. Through the influence of criminology probation has made great strides, at least on paper. As early as 1878 Massachusetts passed a law permitting probation. Rhode Island adopted the practise in 1899 and many states quickly followed. All states now have some kind of probation work with juveniles, and nineteen states have adult probation. The chief defect has not been the tardiness in legislation but the inadequacy of the probation service. As yet probation workers have rarely been scientifically trained, well paid or sufficient in number to carry out their work effectively. The indeterminate sentence conception was first introduced in practise in this country in connection with the Elmira Reformatory in 1876. The American Institute of Criminal Law and Criminology promoted a campaign for the further adoption of

a modified indeterminate sentence, but although indeterminate sentences have been adopted for juveniles they have not been widely applied to adult convicts. Maximum and minimum laws are more common for adults. A maximum and a minimum sentence is prescribed by law and the convict is eligible to parole as soon as his minimum sentence has been served, provided his behavior has been satisfactory. The parole system could be one of the most valuable adjuncts to our reformatory system of dealing with criminals, but unfortunately it is chiefly a paper system today. The parole officers are far too few and too ill trained to handle paroled prisoners properly, and the public authorities are too timid in making thorough use of the parole privileges inhering in the laws of the state. New York and Illinois have parole boards and a parole system which may establish parole as a scientific actuality—perhaps the most important practical step taken since prisons were established a little over a century ago. Laws for the sterilization of the feebleminded, conceived of as measures for crime prevention, have been adopted in thirteen states. The first sterilization law passed in 1905 in Pennsylvania was vetoed by the governor, but the law passed in 1907 in Indiana was sustained. California has been the chief state to enforce such laws, having had performed some six thousand sterilization operations between 1909 and 1929. The United States Supreme Court has sustained the legality of sterilization laws.

Among the important factors promoting the growth of criminal science and its application in criminal and penal practice have been the organizations designed to further the development of criminology in its various phases. The first to be organized were the various prison reform societies, the earliest of which was the Philadelphia Society for Aiding Distressed Prisoners, founded in 1776—the parent of the Pennsylvania Prison Society. The Boston Prison Discipline Society was organized in 1826 by Louis Dwight. The two societies respectively were the protagonists of the Pennsylvania and Auburn systems of prison discipline. International organization began with the first International Prison Congress, held in Frankfurt on the Main in 1845. A new series was started with the Congress of 1872 at London, engineered chiefly by E. C. Wines (1806-79), an American prison reformer. The greatest movement for the reform of penal methods in Europe came in 1889 when the International Union of

Criminal Law was founded by Liszt, Prins and van Hamel. The by-laws which were drawn up at that time embodied the attitude of the modern reformers. They were: that criminality and the means of repression must be examined from both the social and the juridical point of view; that the mission of criminal law is to combat criminality regarded as a social phenomenon; that penal science and penal legislation must therefore take into consideration the results of anthropological and sociological studies; that punishment is one of the most efficacious means the state can use against criminality, although not the only one, and that punishment can never be isolated from other social remedies nor must preventive remedies be neglected; that the distinction between occasional and habitual criminals is essential in theory as well as in practice and must serve as a basis for criminal law regulations; that since repressive tribunals and penitentiary administration have the same ends in view and since the sentence only acquires value by its mode of execution the distinction which the modern laws make between the court and the prison is irrational and harmful; that since punishment by deprivation of liberty justly occupies the first place in our systems of punishments special attention must be given to all that concerns the amelioration of prisons and allied institutions; that so far as short sentences are concerned the substitution of more efficacious measures is not only possible but desirable; that so far as long sentences are concerned the length of the imprisonment must depend not only upon the material and moral gravity of the offense but on the results obtained by the treatment in prison; that so far as incorrigible habitual criminals are concerned, independently of the gravity of the offense and even with regard to the repetition of minor offenses, the penal system ought before all to aim at putting these criminals for as long a period as possible under conditions where they cannot do injury. An international congress of criminal anthropology was organized as a result of the impetus given to criminal anthropology by Lombroso and his followers. The American Prison Society was founded in 1870 at the prison congress in Cincinnati of that year, where many modern criminological doctrines were enunciated. The American Institute of Criminal Law and Criminology, founded in 1909, is through its organ, the *Journal of Criminal Law and Criminology*, probably the most powerful organized body representing criminal science in the United

States. It has had translated into English and published nine of the most important European criminology classics. Law and medicine in relation to crime have been drawn together in the American Society of Medical Jurisprudence. Psychiatrists interested particularly in the social applications of mental hygiene have founded the American Ortho-psychiatric Society, which is especially devoted to the problems of crime and probably does more to advance modern methods in the treatment of crimes than any other American organization. The National Society for Mental Hygiene, founded in 1909, has taken a real interest in the problems of crime, especially in crime prevention. The Commonwealth Fund, a foundation interested especially in mental hygiene, has contributed liberally to research in the borderland between psychiatry and criminology. Organizations such as the federal Children's Bureau have done much to introduce modern methods in juvenile courts and probation. More effective work is being done by these specialized organizations than by the older official organizations in criminology and penology.

CRIPPLES. A cripple is a person whose natural bodily movements are in some way restricted or impaired. The social status of the cripple and the treatment accorded him have varied from group to group and from time to time and have been interrelated with general social attitudes and with concepts of his actual or potential economic role. Among some primitive and ancient peoples the crippled child was exposed

to die and adult cripples were banished or abandoned. Early religious thought ascribed physical deformity to divine punishment for sin or accepted it as an affliction to be endured, attitudes that persist today in backward communities. It is to be noted, however, that the first endeavors to alleviate the misfortunes of cripples came from charitable societies of a religious nature. Throughout the Middle Ages cripples occupied the status of mendicants and children were mutilated to make them valuable as beggars, a practise which dated back to the Romans. The exploitation of crippled children as mendicants roused St. Vincent de Paul to establish in 1634 the first haven for their protection and one of the first institutions for child care.

Beginning with the nineteenth century there has been an incipient recognition of society's responsibility for cripples and an attempt at their constructive rehabilitation. The science of orthopedics by its discoveries of the causes of deformity and by its success in rehabilitation has dissipated the attitude that the cripple must surrender hopelessly to his fate. But everywhere the cripple still suffers not only from economic handicaps due to physical impairments but also from a social attitude which sets him apart in a special class, to be pitied, patronized and tacitly excluded from many of the experiences and privileges of life. As a natural consequence the cripple often develops a special psychological attitude, sometimes of self-pity, sometimes of bitterness, which still further complicates his social relations.

The first cripples to receive constructive treatment were children. For them Jean André Verrel founded the first orthopedic institution at Orbe, Switzerland, in 1780, and institutions for the care and education of crippled children were established in Munich in 1832, in Paris in 1853, in New York in 1863 and later in all parts of the world. In the United States the first state to provide for crippled children at public expense was Minnesota in 1897, and activities or institutions organized in their behalf are now provided by legislation in twenty-four states. Exact figures are not available but it is conservatively estimated that there are over 350,000 crippled children in the United States, chiefly victims of infantile paralysis, bone and joint tuberculosis, congenital deformities, rickets, traumatic conditions, osteomyelitis and accidents. A field canvass made in 1924 in Chicago found 4609 cripples under the age of twenty-one or six in

every thousand of that age group in the population. The same percentage had been found in a previous study in Cleveland and a higher percentage in a New York investigation.

The imperative need of early treatment is revealed by the fact that 83 percent of the cripples examined in Chicago were crippled before the age of six. According to a recent estimate 90 percent of those crippled in early childhood would have escaped deformity if treatment had been given in time. In addition to medical treatment the rehabilitation program for crippled children involves vocational training, and the first school for this purpose was established in Boston in 1893. The contemporary scientific approach to the problem of crippled children includes not only adequate and early medical treatment and vocational training for those already crippled but also elimination of the causes of congenital deformities and the diseases of childhood that bring deformity in their wake. Efforts are also being made toward the promotion of child labor laws that will prevent the employment of children at dangerous trades, and of traffic regulations that will decrease the number of children crippled by accidents. The International Society for Crippled Children, organized in Ohio in 1921, is at present carrying on an agitation for the betterment of the condition of the crippled child.

More than 7,000,000 participants in the World War were crippled. Germany and France each had 1,500,000 disabled, Great Britain 900,000, Italy 800,000, Russia 775,000 (including persons disabled in industrial accidents), Poland 320,000 and Austria, the Kingdom of Serbs, Croats and Slovenes and the United States around 160,000 each. In times of peace workers are crippled through industrial accidents at an appalling rate and public accidents are increasing yearly. The control and prevention of crippling accidents is one of the imperative tasks of modern society. Adequate compensation laws are needed to provide for the victims of these accidents, and medical treatment, occupational therapy, assistance in procuring proper artificial appliances, vocational training and job placement should be afforded the cripple. The last two are especially important if the cripple is to reestablish himself on a sound economic and psychological basis.

The use of insurance compensation for vocational purposes has recently been advocated as the most economical and the swiftest method of rehabilitation. According to one estimate the

cost of such vocational retraining is about one hundred dollars. An actual experiment showed that it was possible to multiply the weekly stipend 400 percent during the period of training and yet to reduce by three fourths the total compensation due at the time of the accident. To overcome the helplessness of the cripple and his tendency to exhaust his compensation before voluntarily seeking occupational training an insurance agency in Wisconsin has instituted a curative workshop, where skills are tested, trades taught, men placed and where the effectiveness of such a plan has been demonstrated. The capacity of industry to absorb handicapped men is not uniform in all trades or all forms of handicap. The employment, for instance, by Henry Ford of large numbers of crippled men is dependent on highly mechanized processes.

In the United States the federal government inaugurated in 1918 through the Vocational Rehabilitation Act an extensive program for physical and vocational rehabilitation designed to reestablish in civil life soldiers, sailors and marines crippled in the World War; and by June, 1926, 90,000 disabled ex-service men had been aided. The Federal Vocational Rehabilitation Act of 1920 extended the scope of the work of the government and provided means for the vocational rehabilitation of civilian disabled persons whatever the cause of their disability, under the direction of the Federal Board for Vocational Education which had been established by the Smith-Hughes law of 1917. By June, 1929, forty-four states were cooperating in joint rehabilitation programs; the federal and state governments share equally the expenses of the work and the states carry out the work under federal supervision. The personnel directing the work ranges from a single director of rehabilitation, as in North Dakota, to a score of highly trained persons, as in New York state. The plan and character of the work also vary from state to state. Disability resulting from industrial accidents accounts for approximately 90 percent of the rehabilitation cases in Pennsylvania and 70 percent of those in New Jersey, while in Minnesota not more than 13 percent of the rehabilitants are classed as industrial cases. Wisconsin teaches cripples between fifty and sixty kinds of craft work in its vocational schools. Virginia has divided the state into a number of orthopedic centers through which it carries on its work. Iowa uses its institutions of higher learning to train its cripples, and other states, such as New York and Ohio, use social

agencies. Most of the rehabilitants are between the ages of twenty and thirty-five years. The Federal Vocational Rehabilitation Act has, however, enabled but a small percentage of disabled persons to occupy remunerative positions. The director of the Board for Vocational Education has conservatively estimated that there are some 225,000 persons permanently disabled in the United States annually and that of this number about 112,000 are vocationally handicapped. With due allowance for those who are too far advanced in years for successful rehabilitation and for those who are hopelessly disabled he estimates a total of 84,000 possible cases for rehabilitation in the United States annually. Only from 1 to 5 percent of these are being rehabilitated. One difficulty lies in the necessity for highly individualized work in each case.

In England and Wales there are some twenty-five orthopedic centers receiving support from public authorities and from a large number of voluntary organizations. The Central Council for the Care of Cripples was established in 1919 to supervise the work for the prevention, treatment and education of crippled children. In Germany the Deutsche Vereinigung für Krüppelfürsorge, formed in 1909, supervises all work in the seventy-eight public and private institutions for cripples. Legislation has been passed requiring employers whose establishments employ more than fifty men to recruit a certain percentage of workers from among trained crippled men. The child welfare law passed in Germany entitling every child to an education "according to his physical, mental and social capacity" has resulted in special provision for the crippled child. Similar legislation is being proposed in Norway, where the handicraft school for cripples, started in Oslo in 1892, has developed into the central institute for cripples, which directs the work throughout the country.

Sweden has a central committee for the care of cripples to coordinate the work of four associations which have three institutions receiving state aid in different sections of the country. Denmark has one institution for the care of cripples founded in 1872. Austria has converted a rehabilitation center for disabled soldiers in Vienna into one for civilians. Holland has a central society for cripples and four private institutions giving treatment and training. The first vocational project for crippled adults in Europe was established in Charleroi, Belgium, in 1908. There are several private institutions for cripples

in France, all under state supervision, and a law passed in 1919 requires the segregation and treatment of cases of articular tuberculosis, which is the chief source of crippling in that country. In Italy, where rickets cripples many children, there are five principal centers for treatment and training as well as several hospitals. Spain has an institute for cripples near Madrid and four asylums for crippled children elsewhere. In the Soviet Union the government is carrying out an extensive program for the rehabilitation of crippled children and adults. An international conference on crippled children was held in Geneva in July, 1929.

The program for the prevention and care of cripples is intimately related to the general economic and social movement. Progress in the work is dependent upon the advance in preventive and therapeutic medicine, upon an elimination of pessimistic and indifferent attitudes, upon a recognition on the part of employers of their responsibility for the safety of their employees, upon preventive measures to eliminate public accidents and upon the active participation of the state in extensive rehabilitation programs which will enable cripples to function in society.

CRISES. A crisis may be defined as a grave and sudden disturbance of economic equilibrium. In a dynamic society the equilibrium between the supply and demand of products and services and between the supply and demand of capital is necessarily unstable, and hence price movements occur. But from time to time a grave and sudden disturbance upsets this complex equilibrium, causing a decided slump in securities and prices. These phenomena are termed crises by economists and the general public.

Scientific research at the end of the nineteenth and the beginning of the twentieth century established the fact that the crisis occurs at the point of transition from a period of expansion to a period of contraction. Certain economists have thereby thought themselves justified in speaking of cycles. But this term labors under the disadvantage of exaggerating the regularity of the phenomenon under consideration. Economic life, like life in general, can hardly be confined within equations and statistical curves. One may speak of cycles, but with the reservation that not all the years of the period before the crisis are prosperous years and not all those after the crisis are years of depression. It is undoubtedly more correct to speak of industrial fluctuations or of alternations of expansion and contraction.

In reality it is the periods of crisis that present the greatest similarity: a sudden fall in prices of commodities (especially metals), credit stringency, suspension of payment by large banks, crashes in the stock market, failures, exceptional gold movements, followed by a decline in production and by unemployment, with repercussions on marriage and birth rates, criminality and political developments.

All crises have one essential feature: one or two rapidly expanding industries find their progress interrupted by reason of a too rapid rise in the cost of production or through an insufficient demand for their products—most often from a combination of these two factors. A decline in prospective profits and a check to expansion follow. Textile industries (at the beginning of the nineteenth century), the railroads (during most of the nineteenth century), electric and automobile industries (at the end of the nineteenth and the beginning of the twentieth century) and the construction industry have been the local points of crises. For a certain number of years the new industries produce the wished for results. At the end of the period of expansion the costs rise and production meets with a slackened demand. A slowing down is

inevitable, hence there is less demand for equipment and a particularly intense crisis arises in metal industries which extends in concentric waves to other industries.

Crises have occurred in all periods of history. But whereas in antiquity and even as late as the eighteenth century the type of crisis most prevalent and most dreaded was that due to a shortage of goods brought about by natural and extra-economic factors, such as crop failure and political disturbances, for the last century and a half crises have been fundamentally due to superabundance or overproduction caused by forces which seem to inhere in modern economic organization. The former type was marked by a considerable rise in prices, the latter is associated with an abrupt and widespread fall in prices. Like that of shortage, the crisis of overproduction is recurrent although not periodical. The date of the preceding crisis is at the most but one element in any forecast of the next. During the whole of the nineteenth century and in the beginning of the twentieth, parallel with the development of capitalism, successive crises are recorded for 1825, 1836-37, 1847, 1857, 1866, 1873, 1882, 1890, 1900, 1907, 1913-14, 1920, 1929.

In the eighteenth and at the beginning of the nineteenth century the crisis was still a "flash in the pan." Speculation played a preponderating role: in the event of new markets for trade, scarcity of products and rising quotations of securities people bought because everything was going up in the hope that the up trend would continue. This would go far and fast. The slump was equally abrupt. In the eighteenth century in France the most typical crisis of this class was that caused by Law's banking scheme, a crisis confined to the stock market but already a perfect type of speculative crisis. In England in 1763, 1772-73, 1783, 1793, 1796, 1810, 1815 and in the war periods (Seven Years' War, wars of the revolution, Napoleonic wars) there was a general anticipation of an unlimited demand for commodities. Prices rose only to come crashing down. Goods were manufactured but found an insufficient outlet. Such crises are very aptly styled by economists periods of commercial crises, for they were chiefly the work of merchants who had become speculators, and the effects of the crises were confined to relatively small social groups. There was another significant feature: the exaggerated rise in the prices of securities would have been impossible without the aid of the banks, which advanced to mer-

chants the necessary funds for their purchases at the enhanced prices. The banks of issue did not as yet regard themselves as regulators of economic activity. They consented to very large advances since the issue of banknotes was not monopolized. The central banks of issue, such as the Bank of England, founded in 1694, or even the Banque de France, founded in 1800, did not have the sole right to issue banknotes. Thus the crises were marked by the failure of great numbers of banks unable to redeem the notes issued during the upward trend of prices. These huge issues of notes, while not the cause of higher prices, were their indispensable condition and support. They furnished those speculating on a rise with the necessary funds for margin. Caught by a sudden decline of prices insolvent speculators found it impossible to pay back their banks. Notes were presented for redemption and could not be redeemed. In the midst of this disorder, however, one bank although as yet having no legally privileged position assumed the leadership: in England the Bank of England, in France the Banque de France. And the logic of facts caused it to assume more and more decisively the role of a reserve. In case of a crisis all turned to it; to it the government conceded advances to help liquidate crises. Crises have had a profound influence upon the development of the functions of banks of issue. The act of 1913 creating the Federal Reserve System in the United States was passed as a result of the crisis of 1907.

After 1825 crises ceased to be commercial, i.e. confined to relatively small groups of speculating merchants, and became industrial, involving ever widening spheres of productive forces. The year 1825 marked the advent of the railway, upon which depended the growth of the iron, coal and steel industries. The equipment used by the textile industry (the first of the great industries) was soon far outstripped by the requirements in metal and coal of the new means of transportation. Thereafter crises ceased to affect consumption goods and their raw materials (cotton, wool, silk) in particular and were extended to the heavy industries providing the means of production (mines, foundries, rolling mills, machinery). Speculation, no longer confined to products, extended to securities on the stock exchange. Heavy industry and the railroads could be financed only through joint stock companies. It was the period in France when the great private banks, such as Rothschild's and Hottinguer's, were no longer rich enough to

furnish manufacturers with the necessary capital. In 1852 the *Crédit Mobilier*, the first great French business bank, was created in Paris. From the beginning of the nineteenth century the banks in England had founded industrial stock companies, whose shares fed the stock market speculation and declined promptly and heavily in value in time of crisis. The banks, which frequently had kept the companies' shares in their portfolios, suffered losses which sometimes proved fatal. From that time onward all crises have been accompanied by the failure of banks whose capital has been invested in enterprises embarrassed by the crisis. They are the victims of runs by their depositors or of losses on their loans or the shares they hold.

Among the banks that have failed through such losses may be mentioned: the Royal Bank of Liverpool in 1847; the banks of Maryland and of Pennsylvania, the Western Bank of Scotland, the City Bank of Glasgow in 1857; Overend Gurney in 1866; the *Crédit Mobilier* in 1867; Jay Cooke and Company, Fisk and Hatch in 1873; the *Union Générale* in 1882; Baring's Bank in 1890; the *Leipziger Bank* in 1900; the Knickerbocker Trust Company (and many others) in 1907; the *Société Centrale des Banques de Province*, the *Banque Industrielle de Chine*, the *Banca Italiana di Sconto* in 1920. On the other hand, in 1929 and 1930 there was no failure of any bank of great significance despite the serious stock exchange crises and a number of lesser bank failures.

It was in the beginning of the nineteenth century that crises began to occasion very large international movements of gold, notably in England in 1825, 1836 and 1839. The excessive imports of commodities at the end of the period of expansion and the sales of securities in London had to be settled with metal once the decline had set in. In 1825 England was in debt to the continent, in 1836 and 1839 to the United States. In 1836 and 1839 the Bank of England raised its discount rate and protected its gold reserve. The act of 1833 had authorized it to fix its discount rate at a level higher than that of the legal interest rate of 5 percent. In 1839 it raised its rate to 6 percent. Crises are accompanied by credit stringency: the merchants have bought but cannot sell at all or must sell at a loss. The manufacturers have produced but they too cannot sell or must sell at a loss. Individual accounts are in arrears. To meet the difficulty recourse is had to credit. The central banks of issue, now the supreme reserve of a country's credit in case of crisis, advance to the

embarrassed trade and industry the funds for payments indispensable if too drastic a liquidation of stocks is to be avoided. The indispensable sales are distributed over a longer period of time or delayed. But to assume this role successfully the central bank must be in a position to increase its banknote circulation. Of all the nations which have had to face general crises, France was long the only one to enjoy adequate legal provisions for central banking. Even today the Bank of England is still limited by the Bank Charter Act of 1844, and it was not until 1913 that the United States established its Federal Reserve banks. The great crises of the nineteenth century have led both theorists and practical men of affairs to discern the significance of elasticity as applied to the currency. A country's reserve bank lends elasticity to its currency and credit system.

As capitalism expands, as crises recur and as their industrial character is accentuated, the industries themselves attack this problem and concern themselves with the stabilization of business. The crisis is now seen to be a concomitant of overproduction: the supply exceeds the demand. Thus, as Juglar pointed out, the crisis ceases to be regarded as a result of the abuse of credit. It has its roots more deeply in supply of, and in demand for, goods. The abuse of credit is itself grafted upon other excesses less apparent but more decisive: upon the excessive development of the means of production and of production itself. The sudden and abrupt drop in prices is not the result solely or chiefly of bull speculations, whose standard dénouement is expressed by a slump and often by a crash. One should distinguish crises of overproduction from speculative crashes. The crisis is distinguished from the crash by its widespread character, by the period of depression that accompanies it and the period of expansion that precedes it. The crisis ceases to be an accident and becomes a link in the chain of the evolution of capitalistic societies. From the middle of the nineteenth century crises have had this aspect.

With the recognition of the economic character of recurrent crises the problem of finding means for their prevention or attenuation came to occupy the attention of the business world. As early as the beginning of the twentieth century the great banks of issue looked upon the discount rate as something more than a mere means of protecting the reserves: the raising of the discount rate became a warning to the business world of the approaching dangers of a

crisis of overproduction. In the years following the war the policy of preventing crises by the instrumentality of credit was designated credit control. The central banks now give warnings to the market irrespective of any modification in the rate of discount; they intervene more directly still by means of open market operations.

The remedial efforts go beyond the organization of credit and the manipulation of the discount rate. Industry attempts to help itself by eliminating competition and by the formation of combinations, thereby gaining a more or less complete control of production and sale. By a rational policy of production and prices it aims to minimize if not eliminate crises of overproduction. The formation of cartels was considered a step in the direction of eliminating crises. As early as 1857 the coal mines of Yorkshire had attempted to check the decline in prices by entering into agreements, but it was the crisis of 1890 that stimulated the multiplication of such cartels, chiefly in Germany, in the industries most affected by conditions of overproduction, namely, mining and metal industries. From their very beginning the cartels sought to minimize crises by a policy which was inspired by the modern conception of this phenomenon. The crisis marks the end of a period of expansion and ushers in an era of depression. The cartels seek to check both the abnormal rise during prosperity and the decline in times of crisis by stabilizing prices, regulating production in accordance with demand and thus avoiding overproduction. The German cartels remained faithful to this policy which inspired their creation. The trust has more complex origins, but it too aims to control and regulate the market. American legislation has made the trusts more discreet as regards the policy to be pursued in case of crises. But very often they maintain prices at a high level after the crisis has arrived. In 1909 and 1929 they based production on demand as did the cartels. The cartel and the trust appear today nearly everywhere as useful instruments for the control of markets. But the stabilization of business by industry itself presupposes a conception of the phenomenon of crises and a theory regarding their nature and cause. The policy of cartels elaborated half a century ago starts with too naïve, empirical and shortsighted an idea: in a crisis they limit production, check the decline of prices and even have recourse to "dumping."

As a matter of fact the phenomena of overproduction are bound up with the shrinkage in

the demand. This shrinkage bears a close relation to the fact that at the end of the period of prosperity costs have risen and the increased production meets less intense needs. To revive the demand, to stimulate it, costs must be reduced; needs that have grown less intense must be met by lowering prices. There is but one means: to reduce the prices of equipment, the prices of raw materials, the selling prices to the consumer. The policy practised by the cartels in Germany and adopted very frequently in the United States in the domain of selling prices in case of a crisis is contrary to economic rationale. Again and again the American trusts have maintained their prices in a crisis, in 1907 and in 1929-30; while the German cartels similarly resisted a decline in the crises of 1900, 1907, 1913 and 1930. This error seems to be of capital importance. In order to reduce costs the prices of iron, steel and equipment must be reduced. This reduction will permit of a reduction in the price of automobiles, rails, cars, turbines. Consumers will be again attracted in spite of the reduction of savings and reserves occasioned by the crisis. The affected industries will recover. Credit is but an element of cost, and cheap credit by itself is ineffective.

Besides the general crises of overproduction there are crises that affect the market for a single product, e.g. coffee, sugar, copper, coal; isolated stock exchange crises; banking crises independent of the general crises; monetary crises (decline in the value of a metal, inflation, deflation). But the general crises in a way synthesize the principal types of crisis. Even the disorders provoked by inflation and deflation are reminiscent of the phenomena found in a period of expansion and a period of depression.

Being a part of a dynamic economic society there is no fixity attached to the characteristics and the behavior of crises. They change with the change in economic organization. In comparing the crises of the beginning of the nineteenth century with recent ones it will be noted that they have affected wider industrial and geographical areas but declined in acuteness.

The changed character and particularly the diminished acuteness of the crises is to be explained by the elaboration of a better credit policy, by the creation of monopolies of production, by a better knowledge and a keener observation of the movement of business. Errors, however, are still possible; the facts are not all discovered. Moreover, dynamism and equilibrium are two antinomic terms, and as long as

economic society remains dynamic its development will be subject to fluctuation. Nevertheless, it would seem that for the term crisis one may henceforth substitute that of depression; it is reasonable to speak today of a world depression rather than of a world crisis.

CRISPI, FRANCESCO (1819-1901), Italian statesman. During his youth Crispi, a Sicilian by birth, was an ardent republican and follower of Mazzini. He took an active part in the Neapolitan revolutionary movements of 1848-49 and was exiled from Italy. Returning after the war of independence in 1859 he prepared and directed with the help of Garibaldi the "Expedition of the Thousand," which liberated Sicily and made it a part of the Italian kingdom. He accepted the monarchical implication of Garibaldi's slogan, "Italia e Vittorio Emanuele," and later, in 1865, as a member of the Italian parliament abandoned completely his republicanism, alienating Mazzini by his famous statement, "La repubblica ci divide, la monarchia ci unisce," in which he subordinated all other considerations to his zeal for unification. Although during the first twenty years of his parliamentary career Crispi was an outstanding champion of liberal measures he was too uncompromising an individualist to form and direct a strong party of the Left. After 1887, however, he occupied a most active and influential position in the political life of Italy, being twice president of the Council of Ministers (1887-91 and 1893-96). Crispi's imperious temperament and the opportunities which he had of manifesting it with only slight opposition in decisive moments of his country's history gave a strong Jacobin cast to his democracy. If in theory he recognized the parliamentary state and the right of the people to govern themselves, in fact he was led to place his own personality above the constitutional powers and to distort *tout par le peuple* into *tout pour le peuple*. His two administrations represent in Italy that stage of political evolution in which democracy is beginning to give way to dictatorship and Caesarism. This tendency is evidenced by Crispi's continuous efforts to carry still farther the process of state centralization and to strengthen the executive at the expense of the legislative, as well as by the severity with which he repressed in the so-called *fasci* of Sicily the

embryonic forms of Italian socialism. Like Mazzini he had a deep hostility to the socialist movement, which to him was synonymous with barbarism, tyranny and egoism and which he was particularly anxious to stamp out because of his suspicion that the movement in Italy was being fostered by France, a country with which for many reasons he felt little sympathy. His policy toward the church alternated between extreme anticlerical measures, on the one hand, prompted by his Masonic sympathies and his resentment at French influence in the Vatican, and, on the other hand, attempts at reconciliation between church and state. Crispi's authoritarian views and his ideal of a strong state, heightened by his friendship with Bismarck, ally him with the expansionist and imperialistic groups which at the close of the nineteenth century were making their influence widely felt throughout Europe. Nourishing dreams of Italian greatness amounting at times almost to megalomania, he advocated the creation of a colonial empire on a scale far beyond the vision and resources of his contemporaries. His spirited but rash ambitions for an empire in Africa came to nothing, resulting instead in his overthrow. The defeat at Adowa in 1896, marking the close of the unfortunate Abyssinian campaign which he had favored and promoted, brought to an end his political career.

GUIDO DE RUGGIERO

Works: Crispi's letters and other writings, as well as the documents relating to his public career, have been arranged and edited by Tommaso Palamenghi-Crispi in the following volumes: *Carteggi politici inediti 1860-1900* (Rome 1912); *I mille* (Milan 1911); *Politica estera* (2nd ed. Milan 1912); *Questioni internazionali* (Milan 1913); the last three tr. by Mary Prichard-Agnetti as *The Memoirs of Francesco Crispi*, 3 vols. (London 1912-14); *Ultimi scritti e discorsi; extra-parlamentari* (Rome 1913); *Lettere dall'esilio, 1850-1860* (Rome 1918); *Politica interna* (Milan 1924, 2nd ed. 1924). His parliamentary speeches may be found in *Discorsi parlamentari*, 3 vols. (Rome 1915).

CRITICISM, SOCIAL. The development of human society has been conditioned by social criticism, which in defending or attacking the status quo has postponed or accelerated change. The most potent social criticism, however, has

often come as a secondary product. In religion such leaders as Confucius, Buddha, Jesus, Mohammed, St. Francis, Luther, were critics of society. Even the ivory tower is not immune to social considerations. Indeed, the practise and appreciation of art depend on certain attitudes toward life which imply social criticism. It is true that the fine arts which have a specialized technique lend themselves to a criticism purely technical or impressionistic—notably music, the most immediately “aesthetic” and abstract. Such criticism applies to other arts in proportion as they approach this ideal, as in abstract painting and sculpture or “pure” poetry. It will be remembered, however, that Matthew Arnold defined poetry as the criticism of life; and even in music the modern masters, Beethoven, Wagner, Chaykovsky, Strauss, have dealt with the meaning of life. Architecture and literature of necessity abound in social implications. Historical criticism of any art involves consideration of the social environment which fostered it; and with the increasing importance of social concepts contemporary criticism, even when aesthetic in intention, has become permeated by social thought.

Science employs the term criticism to denote the selection of data and their impartial interpretation. The complete detachment implied in such a process may often exist in the investigation of nature, but seldom in dealing with aesthetic or social phenomena. Criticism by definition implies judgment, and historically it has been effective through the fervor of its bias more often than by its impartiality.

In the great period of Greek literature the drama, with Aeschylus, was an instrument of aesthetic and social control, becoming an organ of innovation and protest with Euripides and Aristophanes. Socrates in the dialogues of Plato appears as a revolutionist, forcing men to examine the basis of fundamental concepts. Plato himself in *The Republic* initiated a form of social criticism, the imaginary commonwealth, which has had abundant progeny, from the *Utopia* of More to that of William Morris, of Edward Bellamy, of H. G. Wells. Aristotle's criticisms have been constantly invoked in the interest of social and aesthetic conservatism. The relative importance which both Plato and Aristotle attached to social and aesthetic considerations is shown by Plato's exclusion of poets from his republic and Aristotle's dictum that a work of art must be judged by its ethical effect. To the Greeks also we owe two schools of

ethics, stoic and Epicurean, opposed in practise but agreeing in acquiescence in the social order. To these forms of social criticism handed down by the Greeks must be added the orations of Demosthenes, the histories of Herodotus and Thucydides, the biographies of Plutarch and the fables of Aesop.

The Romans took over from the Greeks various types of social criticism: ethics, in the stoicism of Marcus Aurelius and Epictetus and the Epicureanism of Horace and Lucretius; history in Livy and Tacitus; oration and dialogue in Cicero. They developed another form of social protest in the poetic satire of Juvenal and Persius, who became models for the Renaissance and the eighteenth century. The most subversive social criticism under the empire emanated from Christianity, which, however, became conservative through alliance with political government.

Christianity remained the chief form of social control during the Middle Ages. Its fundamental philosophy, enunciated by Augustine and Boethius, encouraged abstention from social interests, and theologians devoted themselves to deducing ecclesiastical authority from divine will. Dante was in substantial agreement with this theology, but his political theory, expressed in *De monarchia*, placed secular empire above the church; and his drastic criticism of the latter institution in practise relegated even popes to hell. Mediaeval social criticism, outside the official and intellectual classics, appeared in the songs of wandering students, the *novelle* of popular story tellers and mock epics such as *Reynard the Fox*, grossly irreverent toward the ruling clergy and nobles. The realistic spirit of this proletarian criticism is present in Chaucer's *Canterbury Tales*. Protest against the ecclesiastical alliance with secular tyranny, anticipating the Reformation, animates the sermons of Wycliffe and the anonymous mass of poetry called *Piers the Plowman*.

The Renaissance involved both a revival of classical culture and the discovery of individual personality. The first aspect manifested itself in scholarly and aesthetic criticism; the second, in curiosity about life and society. To the latter tendency we must attribute the creative literature of the age, the fiction of Boccaccio, Rabelais, Cervantes, the drama of Shakespeare, Ben Jonson and Molière, the revival of history and biography, the rise of autobiography. Among forms involving direct social criticism the most important were the essays of Montaigne and

Bacon, the *Maxims* of La Rochefoucauld, the letters of Madame de Sévigné, the *Caractères* of La Bruyère, the *Fables* of La Fontaine. As modern concepts of the state emerged in the Italian cities political criticism passed from the idealism of *De monarchia* to the realism of Machiavelli's *Prince*. The theory of absolute monarchy called forth a school of apologists, of which Hobbes' *Leviathan* remains a monument. The struggle for parliamentary government in England was carried on by pamphlet and speech as well as by arms. Grotius expounded the recognition of mutual relations between states. The Reformation and the Catholic reaction gave to the church a new social vitality, emphasized by Erasmus and the later reformers. The rise of the Jesuits set in motion a social force felt throughout modern culture. The sermon became a vehicle of social criticism, in France with Bossuet and Fénelon, in England with the long line of churchmen from Hugh Latimer to Jeremy Taylor.

Necessarily education in its adaptation of classical culture to contemporary experience was a leading interest in the Renaissance. In theory it was aristocratic. Castiglione's *Il cortegiano*, Fénelon's *Télémaque*, the long list of English works including Sir Thomas Elyot's *The Boke named the Governour*, Ascham's *Scholemaster*, Lyly's *Euphues*, envisage education as the privilege of the well born, who were to be fitted by training for service to the commonwealth. John Comenius, however, outlined a system of modern education, realistic and democratic.

In general the social criticism of the Renaissance tended toward social stability. Shakespeare's dramas were conservative in their nationalism and their acceptance of the status quo; Luther opposed the peasants in their revolt. Milton's radicalism, however, was indicative of a new trend in criticism which developed in the seventeenth century. He advocated dissent, divorce, revolution, tyrannicide, and wrote the magna carta of the press in the *Areopagitica*. Social protest also characterized many dissenting sects—Quakers, Anabaptists, Levellers. John Bunyan in his sketch of Vanity Fair in *Pilgrim's Progress* set the theme for countless dissertations on bourgeois morality.

The problems of man's life in society dominated intellectual inquiry during the late seventeenth and the eighteenth century, bearing fruit in Montesquieu's political science, Adam Smith's political economy and the social

philosophy of Locke and Shaftesbury. The chief subject of poetry in England was social life, signalized by the revival of satire in Butler, Dryden, Pope and Johnson. Interest in social organization is shown by the popularity of *Gulliver's Travels* and Mandeville's *Fable of the Bees*. The outstanding social phenomenon of this period is the rise of the middle class, which in England found a teacher and prophet in Defoe. For the civilization of this class Steele and Addison in the periodical essay and Richardson in the novel gave models to Europe. The great exemplar of the eighteenth century spirit is Voltaire, to whose influence may be ascribed the philosophic rationalism which found expression in the French *Encyclopédie*, the political experiments of the French Revolution, the utilitarianism of Bentham. The emotional force behind the revolution is found in the romantic criticism of society by Rousseau. Both motives were blended in Diderot and in William Godwin, whose *Caleb Williams* added the emotional appeal of fiction to the formal attack on the British constitution embodied in his *Political Justice*. The example of Richardson and Rousseau in making fiction a vehicle of social reform through education was followed by a school of educational novelists. Mary Wollstonecraft (Mrs. Godwin) was a leader in the movement for feminine emancipation. To the Godwins Shelley owed in part the social theories of *Queen Mab* and *The Revolt of Islam*. Against this revolutionary thought the defense of established institutions was led, for all Europe, by Burke, under whose guidance Wordsworth, Coleridge and Southey swerved from revolution to reaction. This revolutionary period also saw America's active contribution to social criticism. Her mere existence gave plausibility to the romantic conception of the "noble savage" as opposed to "civilized" society. Franklin seems to unite the rationalism of Voltaire and the utilitarianism of Bentham. In the Declaration of Independence Jefferson asserted the principle of revolution, while in the constitution the Federalists embodied the political thought of Burke.

The nineteenth century is distinguished by extended control of nature through science and the rise of the industrial system. Industry called into being an immense working class which gave to social problems a new and menacing character. Science in dealing with this situation fell behind its success in dominating natural forces; nevertheless, it provided the intellectual background and the method of approach to

social problems, notably in the inductive school of political economy and the department of sociology. The resultant of science and industry is seen in the socialism of Fourier and Saint-Simon and more clearly in the communism of Karl Marx and Bakunin, the syndicalism of Sorel, the anarchy of Kropotkin.

In Great Britain, which felt the first impact of industrial revolution, the theory of the democratic state, in which classes should share control according to numbers through representatives elected by universal suffrage, was put forward as a social solvent by the Liberals and received general acceptance throughout Europe. This theory, expounded by John Stuart Mill in his essay *On Liberty*, with its corollary of the abstention of government from interference with private enterprise, was bitterly opposed by Carlyle, whose doctrine of the responsibility of a ruling class, feudal or economic, was set forth in *Past and Present*. Carlyle's eloquence in picturing the misery of the poor and the failure of democracy and laissez faire to relieve it made him the chief influence on English literature during the middle years of the century, especially the poetry of Mrs. Browning and Tennyson and the school of social fiction which included Disraeli, Kingsley, Dickens, Mrs. Gaskell, Charles Reade. Carlyle's philosophy of power had its concomitant in Germany in the individualism of Fichte and Nietzsche and in Hegel's doctrine of the absolute state.

The direct influence of science on social thought is seen in the dominance of realistic literature throughout Europe, especially in the grandiose attempts at social survey by Balzac and Zola. Realism in the English form supplied the background of social criticism in Butler's *Way of All Flesh*. The stage became once more with Ibsen and Shaw a platform of social discussion. The conscious subordination of aesthetic to social criticism is seen in the doctrine of Ruskin and Morris that worthy art can exist only in a good society. Matthew Arnold in *The Function of Criticism at the Present Time* emphasized the primary concern of criticism with the social situation, and Tolstoy in *What Is Art?* made aesthetic criteria depend entirely on social function. H. G. Wells employs numerous literary forms, including history and fiction, for social propaganda, and the fiction and drama of Galsworthy constitute in effect a series of case studies.

In America social criticism found an original expression in Emerson, Thoreau, Whitman,

Henry George. It appears somewhat timidly in the novels of Howells, more boldly in Sinclair Lewis and Upton Sinclair. William James and John Dewey led the philosophical movement known as pragmatism for the subordination of metaphysics to the consideration of social situations.

The war gave to social criticism a new intensity by raising questions—discussed notably by Keyserling and Spengler—concerning the reality of progress and the permanence of western civilization. The war, and its aftermath of social dislocation, also reinforced the tendency of political authorities to curtail free expression of opinion. Absolute government in its modern form of dictatorship necessarily opposes free exercise of social criticism; even the so-called free nations have employed undemocratic methods in defense of democracy. The ease with which the newer publicity devices, cinema and radio, lend themselves to censorship limits their importance as agents of social change. But in spite of suppression social criticism has never been more active than at present, nor has it ever before recognized so clearly its problem of giving free play to ideas while supplying the principle of control within the individual, independent of external authority. This is the common ground on which social critics of diverse schools are united—Tolstoy, Nietzsche, Matthew Arnold, Valéry, Shaw, Unamuno, Dewey and the pragmatists, Babbitt and the humanists.

CROFTON, SIR WALTER FREDERICK (1815-97), British penologist. In 1854 as head of the Irish convict prisons he instituted "the Irish system" of penal administration. He divided imprisonment into three stages. In the first, it was solitary in a cellular prison for eight or nine months of the sentence, depending on the conduct of the prisoner. During the first half of this period the convict was on a reduced diet and without "interesting employment" and was taught "the whole bearing of the 'Irish Convict System.'" Then he was transferred to a congested prison. Here began the second stage, consisting of four grades, passage from or to one or the other depending upon the number of "marks" earned within certain periods as the result of conduct, school progress and industry

The third stage, the essential contribution of Crofton, was the testing ground of the convict before his release on "ticket of leave." In its "intermediate establishments" (analogous to certain American "honor camps") individualization was the ruling principle. In the intermediate institutions there were few officers and little physical restraint, any other practise being held "inconsistent with the principles which the establishments were instituted to enunciate: 1st. You have to show the convict that you really trust him, and give him credit for the amendment he has illustrated by his marks. 2nd. You have to show to the public, that the convict, who will soon be restored to liberty for weal or for woe, may upon reasonable grounds be considered as capable of being safely employed." Following this trial in semifree prisoners were released for the remainder of their term on ticket of leave, analogous to our parole permit.

Crofton's originality lay in welding together into a unified system various features of progressive prison management that had been utilized by Montesinos in Spain, Obermaier in Bavaria and Maconochie in Australia. The Irish system, however, undoubtedly influenced the American adult reformatory movement.

SHELDON GLUECK

Works: A Few Remarks on the Convict Question (Dublin 1857); *A Few Observations on a Pamphlet Recently Published by J. Burt on the Irish Convict System* (London 1863); *The Present Aspect of the Convict Question* (London 1863).

Consult: Carpenter, Mary, Reformatory Prison Discipline as Developed by the Rt. Hon. Sir Walter Crofton in the Irish Convict Prisons (London 1872); Hubbell, G. B., "Report on the Prisons of England and Ireland," in *Prison Association of New York, Twenty-Second Annual Report of the Executive Committee* (New York 1867) p. 95-106; Glueck, S. and E. T., *Five Hundred Criminal Careers* (New York 1930) p. 17-24.

CROLY, HERBERT (1860-1930), American author and editor. Croly attended the College of the City of New York and Harvard University. He was editor of the *Architectural Record* from 1900 to 1906 and of the *New Republic* from 1914 to 1930. A profound student of history and politics, he first attracted public attention with his book *The Promise of American Life* (New York 1909), which contributed largely to the intellectual content of the Rooseveltian Progressive movement and led later to the foundation of the *New Republic*. The argument was that the original American national purpose—a conscious attempt to liberate and enlarge the

personality—had been perverted by self-seeking business and shallow politics, which made a hollow fetish of the doctrine that the Americans were a chosen people who were destined to achieve success by clinging to such traditional dogmas as natural rights and laissez faire. He prescribed a new nationalism to fulfil the promise of democracy by planned and concerted action which would not hesitate to curb "rights" wherever necessary and would not be afraid of being called socialism. His subsequent books, *Marcus Alonzo Hanna—His Life and Work* (New York 1912) and *Progressive Democracy* (New York 1914), continued his study of American political and social institutions. In 1924 he published a memoir, *Willard Straight* (New York), dealing with the man whose financial backing had made possible the *New Republic*. After the World War Croly lost belief in reform through merely political action based on democratic assumptions and called for the pressure in both economic and political affairs of disinherited economic interests, such as organized labor and farmers, groups which, he hoped, would adopt progressively radical programs and philosophies. He abandoned the word liberal as a description of his public policy and reserved it to characterize an attitude of mind which might be held by a member of any party—a belief in the continual discovery of new truth, a scientific, experimental and critical activity. This bent prevented him from maintaining a blind loyalty to any specific cause, leader or group of absolutes. His basic impulse was essentially religious although he adhered to no church. In his later years he concentrated on the discovery of some experimental and scientific way of developing the individual personality, a way which might be imitated, so that new sources of power and inspiration might be brought to bear on the common life.

GEORGE SOULE

Consult: New Republic, vol. lxiii (1930) 243-71.

CROMBIE, ALEXANDER (1762-1840), Scottish economist. Crombie was first a Presbyterian minister and then a schoolmaster in London. His varied writings included several in the field of economics. In *A Letter to D. Ricardo, Esq., Containing an Analysis of His Pamphlet on the Depreciation of Bank Notes* (London 1817) he contested Ricardo's statement that there had been an excessive issue of banknotes and a depreciation in their value. The value of banknotes, Crombie said, must be determined in

terms of their control over labor and commodities and not in terms of gold. Judged by these standards no depreciation of the banknote had been proved. He called Ricardo's reasoning on this question circular and inconsistent, "of that species which may not inaptly be denominated *ambidexter*." Crombie further questioned Ricardo's view that the currency of one country cannot for any length of time be more valuable, as far as equal quantities of precious metals are concerned, than that of another. His objections were based upon the evident differences in gold wages in different countries, control over labor again being used as the measure of value. On the agricultural question he wrote *Letters on the Present State of the Agricultural Interest* (London 1816) and *A Letter to Lieutenant Colonel Torrens in Answer to His Address to the Farmers of the United Kingdom* (London 1832). He advocated long leases for agricultural land and payment of rent half in kind (corn) and half in money. Crombie's importance for economics is to be judged not only by his own writings but by his influence upon Torrens, who dedicated to him the *Essay on Money and Paper Currency* (London 1812) and praised his "acute discernment" and "distinguished talent for abstract and profound inquiry."

W. H. DAWSON

CROME, AUGUST FRIEDRICH WILHELM (1753-1833), German statistician and economist. He was instructor in history and geography at the Philanthropinum in Dessau from 1778 to 1783 and later professor of statistics and cameral science at the University of Giessen from 1787 to 1831. Crome was one of the first to employ geometrical and graphical technique in the presentation of statistics, although he limited the use of this method to descriptive rather than interpretative data. In his influential work *Über die Culturverhältnisse der europäischen Staaten* (Leipzig 1792) he introduced the idea of quadrated surface area maps of countries and peoples. As an economist Crome shared the cameralists' doctrines of population although in later years he became a follower of Adam Smith. In his translation and elaboration of the well known treatise by Leopold II, *Governo della Toscana sotto il regno di . . . Leopoldo II* (Florence 1790; German tr. in 3 pts., Leipzig 1795-97), he advocated an enlightened, benevolent absolutism, a view which he also propagated in his journal, *Germanien* (1807-13). In public life Crome was accordingly

an enthusiastic supporter of Napoleon I and the Confederation of the Rhine. Shortly before his death he published a *Selbstbiographie* (Stuttgart 1833).

PAUL MOMBERT

Other important works: *Europas Produkte . . .* (Dessau 1782; 4th ed. Tübingen 1805); *Über die Grösse und Bevölkerung der europäischen Staaten* (Leipzig 1785; 2nd ed. Frankfurt 1794).

Consult: Kirms, A., *August Friedrich Wilhelm Crome* (Bern 1908).

CROMER, FIRST EARL OF, EVELYN BARING (1841-1917), British administrator. Cromer owes his prominence in oriental history to his long government of Egypt. Born in one of the first financial families of the British Empire he left the army for administration in the Ionian islands in 1861 and in Jamaica in 1865; and as private secretary he was employed by his cousin Lord Northbrook, the viceroy of India, from 1872 until 1876. In 1877 his abilities and his associations with British finance caused the appointment of Cromer—then Major Baring—as British commissioner of the Egyptian Public Debt. Thereafter, with one short break from 1880 to 1883 when he was financial member of council in India, he remained in Egypt as its virtual ruler for a quarter century as commissioner and later as consul general.

The career of Cromer in Egypt coincides with the creation of the Egyptian nation out of a mixed population of various races and religions and out of a province of the Ottoman Empire. The character of Cromer's contribution to that creation is still in controversy; the British consider him the founder of modern Egypt, the Egyptians as a pharaoh who would not let his people go. He had, however, no responsibility for the ruthless repression of the home rule rebellion of Arabi in 1881 nor for that of the rising subsequent to his resignation in 1907; and he undoubtedly ranks with Mehemet Ali in the establishment of the Egyptian state.

There were two principal impediments to the growth of the Egyptian nation. One was the financial burden of debt accumulated by the extravagance of the khedives, culminating in the bankruptcy and abdication of Ismail in 1879. The other was the burden of imperial rule over the fanatical fighting tribes of the Sudan which had been assumed by the ambition of those princes and culminated in the Mahdist rising of 1882. Cromer by insisting on the abandonment of the Sudan enabled Egypt to

set its own house in order. He was in no way responsible for the military catastrophes in which General Gordon and whole Egyptian armies perished. Moreover, his able administration enabled Egypt so to reorganize its forces that in a two-year campaign from 1896 to 1898 an Anglo-Egyptian expedition under Colonel Kitchener ended forever the Mahdist menace. The Anglo-Egyptian condominium over the Sudan, set up by Cromer, although it is today resented by Egypt, nevertheless adequately protects the legitimate interests of Egypt in that hinterland and provides for its independent development.

In internal administration his success is more questionable. He made Egypt solvent—a financial feat that seemed impossible. But it was done by sacrificing the Egyptian peasant for twenty years to the extortionate claims of European money lenders. There was point in the local witicism as to there being “an Evil in Baring too much.” Still more unfortunately for Egypt and the empire he allowed the civic education both of the Egyptian and of Egypt to be neglected. When the inevitable Nationalist movement developed he met it with repression, and the Denshawi incident clouded the end of his regime. His last and perhaps best service to the new nation was to bring to the front the future Nationalist leader, Zaglul Pasha. Nevertheless, history will recognize in Cromer one of the greatest of the proconsuls of the *pax britannica*.

GEORGE YOUNG

CROMWELL, OLIVER (1599–1658), English military leader and statesman. Starting from a desire to secure toleration for the Puritan faith Cromwell developed a dictatorship resting upon a control of the army and popular acclaim. It is impossible to appreciate his political thinking without taking account of his religion. He was perhaps more deeply convinced of his communion with God than any other man of action of his age. Because of this emphasis upon the personal element in faith he was predestined to become the builder of the Commonwealth—a concept which represents the attempt to apply the ancient tribal idea of a brotherhood or fellowship (*Genossenschaft*) to the modern national community. By insisting upon an unexplained faith in the preestablished harmony of

interests of those who “believe in God” it emphasizes the common interests which bind men together without sacrificing the personality of the member or brother (*Genosse*). This symbolical expression points to the core of the political ideas of Cromwell. The inauguration and maintenance of religious toleration as understood by the Independent branch of the Puritan party became his central objective. By linking it to the necessity of maintaining public peace and order Cromwell gave to this objective a definite content which it does not otherwise possess and was enabled to erect thereon a claim for the exercise of dictatorial powers. In 1649 Cromwell decided that Charles I must die because he constituted a permanent threat to the free worship of God and therefore to the public peace. In 1653, dissatisfied with the continued inactivity of the new Parliament, Cromwell and his army council forcibly dissolved it. He became immediately concerned, however, with the question of how to legitimize the power which he had usurped. In his uncertainty as to what would constitute the most legitimate basis for a representative body Cromwell with the advice of his council decided to nominate an intermediary, a constituent assembly. But unfortunately this body, composed of thoroughgoing and literal minded Independents, undertook radical reforms far beyond the limits which the conservative Cromwell considered advisable. Dissolution seemed the only way out and Cromwell did not hesitate. His next attempt to provide a constitutional basis for his authority was the Instrument of Government—the first written constitution designed on a comprehensive scale to organize the government of a modern national community. It rested upon the idea of dividing governmental powers between the legislative and the executive. The office of lord protector created by the Instrument was one of strictly limited powers. He was forced to seek the advice of the council in foreign affairs, its consent in matters of peace and war and its approval in appointments to high office. Laws could not be made nor taxes imposed except by the authority of Parliament, which was empowered even to override the protector's veto. But Cromwell's prerogative of legislating by ordinance when Parliament was not in session enabled him to establish an unprecedentedly liberal ecclesiastical system, to regularize the law and complete the union with Scotland. When the Parliament of 1654 showed a tendency to contest the executive prerogatives, Cromwell

interposed and dissolved it, frankly assuming the role of a military dictator. In spite of growing discontent throughout the land Cromwell was able to maintain his authority because of his hold over the powerful army. Reform by legislation having failed, he divided the country into ten districts administered by major generals and resumed once again legislation by ordinance. Police, public amusements, roads, finances, the condition of prisons, were among the matters affected by this legislation. In the field of foreign relations Cromwell achieved signal success, although his ultimate objective of a league of Protestant commonwealths proved unattainable. The cost of military expeditions consequent upon his aggressive foreign policy led him to summon another Parliament, which again was purged of the opposition by the requirement that each member must secure a certificate from the council of state. In 1657 this new body, believing that the traditional constitutional limitations on English kingship might curtail Cromwell's autocratic powers, offered him the crown. Cromwell refused. But under the less pretentious title of lord protector he introduced many of the trappings of monarchy and heartily approved when Parliament at last adopted the constitution enacted by the earlier body of 1654. This final constitutionalization of the dictator's position together with his military and diplomatic successes abroad seemed to place Cromwell at the height of power, but new threats of royal restoration persuaded him in 1658 to resort again to dissolution of Parliament. Death overtook him while he once more was absolute dictator. His endeavours to set up a constitutional regime had failed.

CROMWELL, THOMAS, EARL OF ESSEX (1485-1540), English statesman. His early life was spent in Italy, Flanders and England as a soldier of fortune, trader and money lender. Attaching himself about 1520 to Wolsey he served him in various capacities and in 1525 acted as his agent in the dissolution of the smaller monasteries. After Wolsey's fall he entered the service of the crown and in rapid succession was appointed privy counselor (1531), chancellor of the exchequer (1533), secretary to the king (1534) and vice regent (1536). His most important duty at first was the manipulation of elections and the management of the House of Commons. In this capacity he transformed the relationship between king and Parliament. Whereas formerly the House was a necessary evil, feared by the king and summoned only in times of extremity, it became under Cromwell's skilful control an active agency of autocratic government. That this new role would result incidentally in a tradition of parliamentary activity and continuity which would later prove the undoing of less able autocrats was not foreseen by Cromwell. He drafted the Reformation statutes and devised the chief administrative expedients for their execution. He enforced, if he did not suggest, the royal supremacy and headship of the church and approved of the executions of Fisher and More. By virtue of his authority as vice regent he superintended the visitation and dissolution of the larger monasteries in 1536 and 1539. His redistribution of ecclesiastical land and property created a new nobility, from whose ranks, ironically enough, were to be drawn in the next century the most active leaders in the overthrow of Tudor autocracy. Cromwell began the ecclesiastical commission later known as the High Commission and issued the injunctions of 1536 and 1538, models of later ecclesiastical administrative measures. He was largely responsible for the increase in the authority of the Privy Council and of the central government, for the loss of political and judicial power by the feudatories and the substitution thereof of the powers of the justices of the peace controlled by the Privy Council. He reorganized and increased the powers of the Star Chamber,

the Court of Requests and the Council of the North and of the Marches of Wales and in general erected the fabric of Tudor government as it remained for a century. Some have thought him the real genius of the period and have left Henry VIII, Cranmer and others subordinate parts, but the better opinion seems to be that the period was the work of a group of men of whom he was one of the most important. The failure of his complicated and too ambitious foreign policy plus the victory of the Roman Catholic reaction in 1540 led to his attainer and cost him his life on the scaffold.

CRONHJELM, GUSTAV (1664-1737), Swedish jurist and statesman. His fame rests chiefly upon his work as chairman of the law codification commission which produced the great Swedish law book of 1734. This ambitious project of compilation, which required almost half a century for its completion, was doubtless inspired by the *Danske lov* of 1683 (*see* CODIFICATION) and was initiated by a request from the Riksdag for a law commission. King Karl XI thereupon appointed in 1686 a commission with twelve members under the chairmanship of Count Erik Lindsköld, who served, however, less than four years. He was succeeded by Count Niels Gyldenstolpe, who died in 1709. Thus Cronhielm, who in turn succeeded the latter, was not only chairman of the commission for over half the period of its activity but it was he who finished the work, and to him the chief credit belongs. Despite the delays caused by the king's foreign wars he was able to submit a draft by 1723; but the criticisms and suggestions of the dignitaries who reviewed it led him to ask for a new commission, whose product was approved by the Riksdag in 1731 and 1734 and went into effect in 1736, the year preceding Cronhielm's death.

The *Sveriges rikets lag* (ed. by W. Uppström, 20th ed. Stockholm 1902), to use the official name of this production, includes eight titles, of which the most important are those relating to marriage, succession, land and buildings, commercial law and penal law. While practically superseded as to the first and last two of these subjects by subsequent legislation the code still forms the basis of civil law in Sweden and Finland and is thus one of the oldest pieces of occi-

dental legislation now in force. It is also distinguished by its indigenous character. For although "both *canonicum* and *Romanum jus* had been eagerly consulted and also German *Stadtrechte* and other prominent foreign laws," its substance is purely Scandinavian except as regards features like the rules of evidence, and perhaps of succession, where canonical influence appears. Its style also has been described as unique, terse and precise, "preserving the ingenuous and rich forms of expression of the ancient law language, with a clear method of presentation." In its avoidance of qualifying definitions the language has been praised as "plain, strong modern Swedish; the only foreign word is testament." This rendered it easy of adoption when submitted to the Riksdag. "The peasant member . . . found the short phrases of the Law-book so clear and homely" that it seemed "to be not a new law but only the old *landslag* rewritten." Altogether it was a notable achievement and entitles Cronhielm to a place among the world's great codifiers and lawgivers.

CROP AND LIVESTOCK REPORTING is an agricultural statistical activity which consists of the collection and dissemination of timely statistical information in the form of estimates and forecasts concerning the acreage, condition, yield, production and prices of crops, and numbers, production and prices of livestock. Aside from forecasting, the concept of crop and livestock reporting is not clearly distinguished from an annual or more frequent periodic agricultural census, except that crop and livestock reports are usually based upon sample or judgment data selected so as to be representative of the universe or area from which they are taken. These reports, especially when used to forecast production or price before harvest, must be compiled and published within a short time after the date to which they refer and as early in the growing season as practicable in order to be of maximum value to producers and handlers of farm products.

Crop and livestock reporting has been performed by governmental and private organizations for many years. About the middle of the

nineteenth century several attempts were made by European governments to start crop reporting systems. The most noteworthy effort was in Prussia. In the United States as early as 1855 James T. Earle, president of the Maryland State Agricultural Society, endeavored to inaugurate a system of crop reports that would protect the farmer against "the artful practices of speculators and others" who had superior information. He planned to have intelligent farmers report to the various state agricultural societies and the societies disseminate reliable information based upon these reports. He recognized, however, that this function "should properly be imposed upon an agricultural department." In 1863, largely as a result of the agitation of farmers and farm organizations, the United States Department of Agriculture issued its first regular crop reports. Since then reports have been published regularly and the service has been expanded so as to include practically all of the crops grown in the United States and to provide additional information about each crop.

At present most of the countries of the world maintain some form of crop reporting service. There has been a marked expansion in official crop reporting since 1905, when the International Institute of Agriculture was established at Rome to act as a clearing house for crop reports and other agricultural information. The development of rapid and easy means of transportation and communication and the widening of the markets for agricultural products, coupled with specialization in crop and livestock production, has resulted in a world wide demand for more complete and accurate agricultural statistics and has materially aided the expansion, improvement and standardization of crop reporting methods throughout the world.

In the United States the crop reporting service is a unit of the Bureau of Agricultural Economics in the Department of Agriculture. It maintains a staff of trained statisticians in Washington and has a field office with an agricultural statistician in charge in almost every state. Before 1914, when the entire crop reporting service was placed under the classified civil service, practically the entire field staff was composed of political appointees. The technical workers of the crop reporting service, however, are now selected only after they pass a rigid civil service examination covering agriculture, economics and statistics. In thirty-seven states the crop reporting work is conducted cooperatively by the federal department and the state

department of agriculture or the state agricultural college. Most of the basic data for the crop reports are furnished by nearly 300,000 voluntary crop correspondents, most of whom are farmers. The correspondents are divided into groups; some report directly to Washington and others to the field offices. For the more important crops the information of one group is checked against that of another. All crop reports are prepared or passed upon by a Crop Reporting Board composed of crop statisticians drawn partly from Washington and partly from the field offices. It meets monthly. Because of the great influence that these reports have upon agricultural prices all persons connected with the crop reporting work are prohibited under severe penalty from giving out information in advance of the time set by law or department regulation for the release of a crop report or from speculating in any product of the soil.

Crop and livestock reporting as now carried on in the United States and in other countries may be divided into several parts: estimating acreage, condition of crops and production after harvest, forecasting yields and production in advance of harvests, reporting farm and market prices and estimating livestock numbers and production. In addition the United States issues intention to plant and outlook reports.

The methods used to determine the acreage planted to various crops vary widely. Several countries, England, Scotland, Denmark and Hungary, for example, take an annual census of acreage and compile it in time for use during the current season. In some countries the estimates of changes in acreage are based upon the judgment reports of local officials or farmers. In others where changes are slight the acreage is held constant between census periods. In still others the acreage estimates are based upon sample data collected from individual farms so selected as to be typical of the area from which they are drawn. This is the method now generally used in the United States; the acreages shown by the most recent agricultural census are used as the base from which the yearly changes are calculated. Questionnaires are mailed in June of each year to a large list of farmers requesting them to report for their own farms the acreage planted to each crop for the current and previous year. In September a second questionnaire is distributed to farmers by the rural mail carriers on which they are requested to report the acreage of each crop they have harvested and expect to harvest. In states where the harvest is

normally late and also in years when crops are late generally this inquiry is delayed until October.

Three methods are used for calculating acreage changes from such sample data: a direct comparison of the reported acreage for the current year with the previous year on the same questionnaire; matching reports from identical farms for successive years and calculating the changes; and a comparison in successive years of the percentage that the acreage of each crop forms of the total acreage in the sample reports.

The size of the sample required to secure accurate estimates depends upon the particular crop. For a crop such as corn, which is grown on nearly all farms, a sample which includes about 2 percent of the acreage will generally give a fairly accurate indication of the change that has occurred, while with some of the minor crops as high as 20 percent of the acreage needs to be included in the sample to insure stability. A great deal depends upon the manner in which the sample is taken and how it is handled. Stratification of the sample according to size of farm as well as homogeneity of area represented, with proper weighting, contributes materially to accuracy. A system of compulsory reporting by all farm operators within certain selected areas, such as a township per county, would no doubt materially improve the representativeness of the sample secured.

An objective method has been developed for measuring the percentage of acreage change from year to year by the use of a crop meter attached to an automobile. By means of this meter the number of linear feet in each crop along selected routes is measured each year and the changes calculated in percentages. The laws of a few states require assessors to take an annual enumeration of the acres in crops on all farms. These enumerations afford a valuable check upon estimates made from sample data.

There are three rather well defined methods used throughout the world to express the condition of crops during the growing season. These may be termed as follows: the percentage method, with 100 representing normal or average, as used in the United States, Canada and England; the numerical symbol method, using figures ranging from 1 to 6 or 6 to 1 to indicate the relative condition, as used in Germany and Denmark; and the descriptive method, where adjectives ranging from "excellent" to "very poor" are used instead of numbers, as in Spain and Rumania.

The term normal is used in the United States with a meaning different from that which it has in other countries. Crop correspondents are instructed to report the condition of a crop not as a percentage of an average crop as in most countries but as a percentage of a full or normal crop, meaning the hypothetical condition of a crop which starts out and continues to grow under favorable conditions and which remains free of injurious agencies.

The countries which report to the International Institute of Agriculture at Rome are requested to report the condition of growing crops in the form of a percentage, 100 representing an average condition, which if uninfluenced by abnormal circumstances would give a probable yield per unit of surface equal to the average yield of the past ten years. Most countries report to the institute as requested by converting their numerical symbols and descriptions into percentages, but usually publish their reports locally in the form in which they are gathered.

Estimates of production after harvest, usually obtained by multiplying the acreage by the average yield reported by correspondents, have been made and published in a large number of countries for many years. Their purpose generally is to supply annual production figures between the regular census years. In the United States such estimates are made immediately after harvest and are revised in December of each year. In the case of cotton the reports on ginning published by the Bureau of the Census between September 1 and January 16 may be used to check such estimates.

The making of official quantitative forecasts of probable yields and production in advance of harvest is a comparatively new activity and was begun in the United States in 1912. The idea has gradually spread, especially since 1920, so that many countries are now forecasting yield and production prior to harvest for the more important crops. Yield forecasts are usually made either by interpreting the condition reports in terms of probable yield per unit of surface on the basis of past relationships between reported condition and final yield or by asking reporters to make direct estimates of the probable yield per unit of surface instead of in percentages or symbols.

The most common method of making a yield forecast is to plot the reported condition or probable yield against the final yield on a dot chart for a series of years and draw the line of best fit. When the condition or probable yield is

computed for the current month, the final yield for the current year can then be readily predicted from the chart. This is done on the assumption that the final yield per acre for the current year bears the same relation to the condition of the crop for the current month as the final yield during the preceding years has borne to the condition for the same month during the preceding years. Some work has been done in the United States and other countries in developing methods of forecasting yields from weather data, but further progress awaits extensive research and investigation.

Until recently forecasts of production in the United States were simply a mathematical interpretation of the condition reports based on the relation which had existed in previous years between the condition reported at a given time and the final yield. The forecast for the final production of a crop was secured simply by multiplying the estimated acreage by the forecast final yield. Since 1927 the Crop Reporting Board has gone much further and is attempting to forecast the final yield by considering weather and other factors in addition to condition reports. This has resulted in much more accurate forecasts, especially for cotton and potatoes.

Unless forecasts of production made in advance of harvest bear a rather close relationship to the actual production they are detrimental rather than helpful. Because supply is generally believed to be the dominant factor in the determination of the leading agricultural prices, official forecasts of yield or production have a decided influence upon prices. Governmental forecasts therefore have been severely criticized when they have been inaccurate. Several sporadic attempts have been made in the United States to abolish the reports by certain groups of farmers who believed that the official reports benefited speculators and injured producers; while the accuracy of certain reports, especially those relating to cotton, has been frequently questioned and several congressional investigations have been made. Technicians have frequently attacked the condition reports, particularly those made early in the season, maintaining that they are merely averages of guesses having little validity, and have often criticized the early forecasts as being worse than useless. For example, in 1917 Henry L. Moore showed that during the preceding years in the United States the correlation between the actual yield of cotton and the May prediction of the Department of Agriculture was minus and the June

prediction was only .29. In recent years, however, the Department of Agriculture has generally postponed making forecasts of yield until such time as experience has shown there is a reasonable degree of relationship or correlation between the forecast and final output. Formerly forecasts were issued for spring wheat, oats and barley as early as June 1; the first forecasts are now made as of July 1. No forecast is now made of the cotton crop until August 1; formerly the first forecast was made as of June 25.

Price reporting of crops and livestock varies widely in character and scope in different countries. In the United States farm prices (prices received by farmers for the produce on the farm or in the local market) are secured and issued monthly on most of the important farm products. These prices are collected by questionnaire. Market or wholesale price reporting covering vegetables, fruits, livestock, eggs, poultry and other farm products is carried on by the Department of Agriculture at most of the important central market cities. These prices are obtained by trained market price reporters. The department also collects quarterly prices on articles bought by farmers.

Livestock reporting is much less developed than crop reporting; few countries attempt anything more than annual estimates or enumerations. Wool estimates are issued by a number of countries. Little has been done as yet to estimate milk, egg and poultry production. Since 1923, however, livestock reporting in the United States has been materially expanded; a number of special reports are now issued during the year covering hog supplies and the number of cattle and sheep in feed lots.

As an aid to farmers in adjusting production to market demands the United States Department of Agriculture initiated in 1923 a new series of reports which have come to be known as intention to plant and outlook reports. Intention to plant reports are based upon returns from a large number of farmers and are made in March and September. In June and December the intentions of farmers with respect to hog breeding are secured in connection with livestock surveys made through the rural mail carriers. The intention reports give farmers the opportunity to readjust their production programs at the last minute on the basis of the plans of other farmers. Another report is issued in January of each year in which the outlook for each of the more important commodities is frankly discussed and forecasts are made of the

probable trend of production and prices. These reports are based upon information gathered from all parts of the world through the International Institute of Agriculture, American consuls, commercial attachés and the offices of the Department of Agriculture in foreign countries. Supplementary outlook reports on special commodities are issued throughout the year.

Private crop and livestock reporting undoubtedly existed long before official crop reports were started and has continued to exist along with governmental reporting. At present a number of the large grain and cotton organizations conduct crop reporting systems of their own with trained statisticians in charge, who keep in close touch with the situation through crop correspondents and by travel. Some of these organizations publish monthly reports; others collect the information for the exclusive use of themselves and their clients. Probably the most important private crop reporting organization is Broomhall's agency, whose main office is in Liverpool. It issues crop reports, market quotations and other statistical data about the grain trade on the basis of information gathered from its agents and correspondents located in all of the important grain producing countries. It is in a way an official statistical representative of every important grain exchange in the world. A number of individual firms in the cotton and grain trade and several newspapers and railroads also collect and publish crop information. The continuance of private crop and livestock reporting has been primarily due to a lack of faith in the accuracy of governmental reporting and to the constant desire of individuals connected with the trade in agricultural commodities for more accurate or inside information on the basis of which they may make a speculative profit.

Official crop reports are widely used by many classes of people, especially producers and marketing and distributing agencies, because these reports furnish the essential facts of production and supply of food and raw materials unbiased by personal interest. They are of value to farmers as a guide in adjusting acreage of particular crops to meet market requirements and in deciding when to sell. They are of indirect value to farmers in that they prevent the issuance or minimize the effects of biased, false or misleading private reports. They probably tend to reduce speculation, because increased certainty of supply helps to stabilize prices and reduces the speculative margins necessary where

uncertainty exists. They furnish information as to supply to produce exchanges, boards of trade and livestock exchanges. Agricultural extension workers use them largely in preparing agricultural programs. They enable bankers to provide in advance for the funds needed in financing crop production, storage and marketing. They enable railroads to estimate the number of cars that must be available for moving crops and livestock. They furnish insurance companies with data on which to base crop insurance and place farm loans. Manufacturers and merchants use them to determine quantities for manufacture, to decide where to distribute their products geographically and to determine where to concentrate selling campaigns. They indicate to meat packing establishments the probable future supply of the raw product, thus aiding them in determining whether to accumulate stocks or to sell quickly. Crop and livestock reporting data are also widely used by economists and business analysts in studies of industrial, commercial and agricultural conditions.

CROWD. Crowds have been variously defined as (1) more or less dense aggregations of people in the same locality; (2) face to face groups of people responding similarly to the same stimuli; (3) according to Martin, people everywhere responding similarly to the same situation in such a manner as to secure release for their repressed desires; and (4) face to face groups responding wildly and largely without order and uniformity to suggestions to which they have previously been conditioned. The last definition corresponds more closely to the mob (*q. v.*), which may be regarded as a highly emotionalized and unstable form of the crowd. The first represents primarily the popular conception of crowds. The second is sufficiently inclusive to cover the mob but is not coterminous with it, since crowds so defined may possess a high degree of stability, if not of rationality. The third is a product of the influence of psychoanalytic theory upon the psychology of the group and it deviates from the traditional concept of crowds, which holds that they must be face to face groups.

Distance contact groups whose members respond to the same stimuli or intercondition one another have been called publics. The crowd is a subdivision of the group and is in turn inclusive of the mob. The other major and co-ordinate face to face division of the group is the assembly, whose members are usually organized into a formal association, meeting for the discussion or resolution of fairly specific problems and following a program usually prepared beforehand. The crowd is generally more casual in occurrence and purpose, less well organized or not at all organized, and it usually has no preliminary program. Those who seek to control the crowd and direct its behavior may, however,

be well organized and have a definite purpose and a carefully prepared program.

Casual and highly fluid crowds, such as ordinary street aggregations, are largely without conscious interconditioning of responses, and therefore their members are not in active communication. They are, however, usually not without some degree of organization, resulting from the fact that each member is responding to certain highly stereotyped stimuli, such as traffic signals and the conventions of the street. These responses result in mutual adaptation and a consequent organic unity, although the unity is primarily unconsciously controlled and the units of the aggregate are constantly changing. Moreover, all of the members of such fluid and casual crowds are ordinarily possessors of very similar or even identical behavior patterns previously conditioned to respond to the same stimuli, unless they speak different languages and are drawn from very unlike cultures. If such effective stimuli are presented by a fire alarm, a policeman, an accident or a street speaker, the fluid, casual crowd may suddenly be transformed into a fixed organic crowd; and its organic character may be greatly intensified by active interconditioning, especially by the interchange of observations. Such an organic crowd may further become functional by the development of a common pattern of behavior under the pressure of the policeman or a squad of soldiers or under the pull of strong excitement and curiosity, as when children follow a band or people participate in a parade.

In order that the crowd may be brought to its highest organic development, where it functions as an interconditioned psychic unit organization, there must be a leader or at least a principle or sentiment which has some concrete physical embodiment in conversation or in a bulletin or newspaper generally available. The integration of the crowd in such cases results when previously conditioned like behavior patterns of individuals are made to respond simultaneously to the leader, phrase, principle or stereotype. If there is also complementary interconditioning of responses among the members at the same time that there is parallel response to the external stimulus, the organic character of the crowd is greatly emphasized. Such a crowd is truly purposive but it is not necessarily rational. It may become rational and thus pass into the category of the deliberative assembly; or it may be swayed so strongly by emotion that it becomes a mob. Mass meetings generally and

political conventions not infrequently illustrate these more organic types of the crowd. Sometimes they result in riots and even in revolutions.

The crowd psychology school, represented by such writers as Le Bon (*The Crowd*), Tarde (*L'opinion et la foule*, Paris 1910), Sighele (*La folla delinquente*, 2nd ed. Turin 1895) and Ross (*Social Psychology*), have attempted to construct a social psychology upon the behavior of the individual in the crowd. Ross and Le Bon have emphasized the highly emotional character of behavior under the impact of crowd stimuli. The individual becomes excited, loses self-control, fixates his attention upon the leader or other stimulus and abandons himself to suggestion, while his behavior is reinforced by the perception that others are responding similarly. Such behavior is uncritical of motives, highly credulous and without inhibiting moral scruples. Under such conditions conduct may revert to the primitive. But such behavior is also exhausting and the crowd easily changes its object of attention or allegiance; it is fickle. Martin further emphasizes the weakness of inhibitions in crowd behavior, which permits repressed desires to secure expression.

Behavior of this sort, which is to be seen strikingly when the crowd is a face to face group, takes on further significance when it is extended, as by some of the crowd psychology school, to characterize the broad sweep of the behavior of human societies, especially in times of stress. All the mobility, fickleness, credulousness, hysteria and so-called sadism which have been attributed by one writer or another to the face to face organic crowd are from this point of view seen as characteristics of any society which has for the time being converted itself into a crowd. At such times the society, in order to convince itself and others that its motives are not antisocial and egoistic, rationalizes its behavior by inventing high sounding shibboleths and righteous principles. Such pious inventions have enabled religious dogmatists to burn their rivals at the stake with a clear conscience and a capitalist controlled state to promote war for the acquisition of markets and raw materials. While such an extended interpretation is clearly inadequate as a basis for crowd psychology it is of distinct value in indicating that the peculiar mentality characteristic of crowds may be extended under the influence of propaganda or excitement and by means of facile instruments of communication to any sort of society or social grouping. Thus the psycho-

analytic approach to the psychology of the crowd throws light upon collective motivation not hitherto adequately appreciated. It is at this point that the character of the crowd approaches most closely to that of the mob.

CRUCÉ, ÉMERIC (c. 1590-1648), French writer on international law and economics. Little is known about his life. He published an edition of Publius Papinius Statius which was fiercely attacked by contemporaries. His semi-anonymous book, *Le nouveau cynée ou discours d'estat représentant les occasions et moyens d'établir une paix générale et la liberté du commerce par tout le monde* (Paris 1623; a copy in the Bibliothèque Nationale of Paris bearing the name Ém. Crucé is dated 1624), appeared when Grotius, also in Paris, wrote his *De jure belli ac pacis* (1625), and consequently received little notice; until 1890 the exact name of the author was uncertain. Crucé, assuming the role that Cincius held at the court of King Pyrrhus, detailed a plan of reform of international relations and national politics. The *Nouveau cynée* advocated peace and prosperity to be achieved by the creation at Venice of a permanent international assembly including Christian and non-Christian princes and states to which were to be submitted all international differences; the proclamation of universal free trade; the acceptance by the states of responsibility for the social welfare of their subjects. Crucé maintained there was an intimate relation between peace and economic progress. According to him the main productive forces are agriculture, commerce, industry and a few sciences, such as medicine and mathematics. A convinced free trader 150 years before Adam Smith, he opposed distinctions between native and foreign merchants. He advocated stabilization and uniformity of coins, weights and measures.

CRUELTY TO ANIMALS. *See* ANIMAL PROTECTION.

CRUSADES. The crusades have been regarded primarily as holy wars, but actually they are much more complex in character. They were also in part feudal forays, commercial and colonizing expeditions and a phase of the long struggle between eastern and western peoples. The eleventh century was a period in which the spirit of asceticism was widespread in western Europe; men and women were seeking salvation through strict monkish discipline, fasting and self-torture and by long and dangerous pilgrimages, the greatest of which was to Jerusalem, "where His feet have stood." As a penance for the most heinous crimes this pilgrimage gained rapidly in popularity; one hundred and seventeen were recorded in the eleventh century before the first crusade. The advance of Turkish forces north and west interrupted the pilgrimage route.

When the Byzantine emperor appealed to the pope for aid against the Moslem invaders of his territory, Urban II saw an opportunity to heal the schism between the Greek and Roman churches and to reestablish his position as the head of Christianity, threatened by an antipope who had exiled him from Rome. He summoned a council at Clermont in November, 1095, to mobilize Christendom for a united effort against the Turk. His appeal was directed to a group of feudal chieftains. These nobles, especially the French, were warriors by profession and trained to fighting in a period of great unrest. Normans had conquered England, southern Italy and

Sicily and had attacked the Byzantine Empire. Italian cities had successfully raided the Levant and were seeking new channels for trade expansion. The Spaniards, aided by adventurers from southern France, were struggling against the Moors. Simultaneously feudal lords clashed on home fields in recurring private wars. The development of chivalry had raised war and adventure to the status almost of a *summum bonum*; moreover, war had proved an excellent means for landless men to secure property and position, and the marketable plunder of victory was an enticing bait to a growing trading class. Upon such emotions and interests Urban played in his appeal at Clermont. He depicted the atrocities committed by the Turks and the profanation of the holy places, the possibility of booty and the advantage of fighting in a holy war rather than imperiling their souls by fighting against Christians at home. He incited them to march under the leadership of Christ to recover His grave, with the assurance of booty for the survivors and paradise for those who perished.

Thousands pressed forward to take the cross, non-combatants, women and children as well as warriors; the first crusading host which set out in 1096 was a mob with a nucleus of fighters. The main contingents came from France and southern Italy with detachments from every land in Europe. After three years of effort Jerusalem was taken. Four Latin states were set up: the kingdom of Jerusalem, the principality of Antioch, the counties of Edessa and Tripoli. Venice, Pisa and Genoa received exceptional trading privileges in payment for the aid lent by their fleets in capturing the seaports of Syria and Palestine.

This first success was impermanent. In 1145 Eugenius III called for a second crusade, whose great preacher was St. Bernard. A series of expeditions followed throughout the twelfth and thirteenth centuries and projects were entertained as late as the opening of the sixteenth century, but the heyday of the enterprise was from 1096 until the capture of Jerusalem by Saladin in 1187.

In this period a constant stream of pilgrims came and went between the Holy Land and the West. Small permanent colonies were set up by the Europeans or Franks, composed mainly of warriors, clergymen and merchants from Italy and Marseille. But Damascus, Homs, Hama, Aleppo and other strongholds remained in Moslem hands, and at all times almost every Frankish possession was within a day's ride of a

potential enemy. From necessity the Franks mixed with the natives, employing them to cultivate the soil, to carry on the arts and crafts, even to fight in crusading armies. The natives included Syrians, Maronites, Jacobites, Greeks, Armenians, Georgians, Jews, Samaritans, Arabs, Turks, Egyptians and many others. Lacking bonds of unity, divided by their religions and long accustomed to foreign rule they submitted without resistance after the Turkish or Egyptian garrisons had been dispossessed. Inter-marriages were common. The kings married Armenian or Greek princesses; in the second half of the twelfth century some kings were three fourths oriental by blood, and the same was probably true of many so-called Franks in the other classes.

This mongrel people desired to live in peace and had no zeal for the holy war. Even more true was this of the Italians who were in the East for trade. Although adventurers seeking fortunes provoked trouble, the intermittent fighting was frequently between Christian princes, who sought allies among the Moslems or supported rival Moslem princes in their internal quarrels. Only twice was there unity on either side, during the first crusade and again when Saladin attacked the Christians. Chroniclers have dwelt upon the first crusade, on the heroic deeds of Richard the Lion-Hearted or of Saladin, on the defense of Acre in 1291. Far more important for an understanding of the crusades is a study of the peaceful intercourse which went on even after the third crusade until the loss of the last Christian possessions in the Holy Land.

The first contacts came in battle. The crusaders soon learned to admire the Moslems for bravery and consequently were more ready to admit the possibility of their having other good qualities. The inhabitants of Syria had inherited much from the old Greek culture and even some of the Turkish rulers were patrons of learning. Damascus, Antioch and Tripoli were centers of education. Many Saracen rulers were more civilized than the western warriors; moreover, they had some tastes in common. As they hunted over the same territory under a hunting truce agreement they met frequently and soon began to trade horses, dogs and falcons. Trading in general brought the Franks into friendly and constant contact with the Arabs, the middlemen in the commerce with the extreme Orient. Traders from Mosul had warehouses at Acre and were protected by the Templars. Safe

conducts were freely given and duly honored by both Moslem and Christian rulers.

Intimate association led to assimilation of oriental customs. The Franks frequently preferred Arab dress, more suitable to the climate, and also the more appetizing Arab food and houses more luxurious than those to which they had been accustomed. They borrowed Arab doctors, who had inherited Greek methods of treatment in great contrast to the western doctors, who freely used the knife or the axe to cut off the offending members. Although the crusades were accompanied by numerous violent and atrocious attacks on Jewish communities in Europe, the Franks in Palestine imbibed some notions of tolerance from their contact with peoples of so many different religions.

The new ideas and the new needs acquired in the East were transferred to the West by men who returned home, and Italian merchants eagerly fostered the demand for eastern commodities which brought them so much gain. The literature of the twelfth and thirteenth centuries indicates the widespread interest in oriental luxuries, which rapidly became necessities for the nobles and caused a great increase in the cost of living. As the income of nobles, from customary dues, was almost fixed and could not easily be increased except by the acquisition of more property and as the nobles felt obliged to be lavish in expenditures, many of them fell into debt and were finally ruined. The English pipe rolls lists of insolvent debtors substantiate poetic reports of the passing of nobles' property into the hands of rich villains.

As the church prohibited the charging of interest, money lenders were usually Jews; their clients were the nobles and the clergy. Since interest rates were high (about 52 percent a year in England when the security was excellent), the borrower was often in a desperate plight. To this fact is to be attributed much of the propaganda which led to hatred of the Jews and finally caused their banishment when a class of Christian bankers had arisen to take their place.

The merchants profited by the demand for luxuries and by the introduction of a money economy. The latter was, at least in part, a result of the demand for ready money on the part of crusaders or pilgrims. Merchants became more important, towns increased in size and prosperity, the third estate was favored by kings who needed its money and support. The Italian cities profited most and extended their trade to

all parts of the Mediterranean. Larger vessels were built to carry pilgrims or crusaders, their horses and supplies and the lumber so much needed in the Orient. Improvements in navigation followed, such as tacking and the use of a compass. These vessels made it possible to carry to the West large cargoes of oriental wares at comparatively slight cost for freight. One result of this international trade was the development and widespread use of codes of maritime law.

Travel and trade led to increased knowledge of geography and interest in the lands traversed or from which the wares came. Contacts between different peoples, together with the ample leisure on their voyages, led to an exchange of tales and information which enriched the literature of western Europe. This was the golden age of story telling; the Orient, Scandinavia, Ireland, Cornwall, Brittany, all contributed and the various elements were incorporated into the jongleur literature of France and thence spread to other lands. Contemporary tales reveal the eastern origin of such chivalric institutions as heraldry. In the art of war new methods were learned, partly from the Byzantines, partly from the Arabs.

Contacts between followers of various religions caused discussion of their relative merits. Peter the Venerable, abbot of Cluny, had the Koran translated so that he might study it. Eastern heresies followed the routes of trade into western Europe. The militant faith of the age was manifested not only in crusades to the Baltic lands and Spain as well as to the Orient, and in the persecution of heretics, but also in missionary enterprises. From the thirteenth century onward the Roman church sent its servants to convert the peoples of Asia.

At home the crusades enhanced the power of the papacy and the wealth of the church. Indulgences first given for crusading service soon became purchasable and the system of sales began which was to have so much importance in the subsequent history of the church. Direct taxes based on values were levied by both kings and popes for their crusades, and these precedents may have made it easier to exact such taxes later for other purposes, thus beginning a system destined to supplant that of the feudal dues. But it is hazardous to attempt to assess the influence on the developing monarchies or the papacy; in some ways the feudal lords and the pope, in others the kings, seem to have been benefited. On the whole, it is difficult to summarize the direct results of the crusades; the

changes they produced had been prepared for in part through earlier contacts between the East and the West, and later contacts continued to introduce changes. Many of the results which have been claimed cannot be proved. The crusades began as an international movement but seem to have aroused a spirit of nationalism; they began largely as a religious movement and ended almost entirely as politico-economic expeditions. It is safest to say that the crusades accelerated tendencies already visible and, most important, broadened the cultural horizon of the West.

Contemporaries of the first crusade believed it to be the work of God. The failure of the third crusade in the next century; crusades against Christians, such as the freebooting attack on Constantinople with all its horrors; the peaceful negotiations conducted by Frederick II with those who were in theory the unpardonable and infidel enemies of the Lord; and the growing domination of secular motives, ill cloaked in religious pretense (particularly in the crusade undertaken against the Albigensian heretics in southern France by the land hungry nobles of the north), caused some to doubt. The antagonism of supporters of the empire to the pope, the patron of crusades, caused hostility, and in Ratisbon the death penalty was decreed against anyone who took the cross. Yet as a whole the general feeling for centuries was that crusades were a holy war and also a necessity to check the victorious advance of the Turks. By the eighteenth century opinions had changed and Voltaire expressed the prevalent feeling that the crusades were a foolish undertaking, participated in by criminals. At the beginning of the next century one author apostrophized Pope Urban II, author of the movement, as one against whom "seven million men will cry out at the day of judgment."

Renewed study of the Middle Ages attendant on the nineteenth century romantic movement produced two great histories of the crusades, by Wilken in Germany and Michaud in France. The latter work, written under romantic influence, was widely copied in France, England and the United States. In Germany the crusades were thought of as a migration (Heeren), a defensive war, an episode in the long struggle between the Orient and the Occident, or as a colonizing movement (Kugler). Stevenson defined them as "military expeditions to establish and maintain a Latin power in Syria." It is impossible to give a single explanation. The eco-

conomic motives cannot be neglected, but it was the religious motive which gave the crusades their peculiar character.

CUJAS, JACQUES (1522-90), French jurist. He taught at Toulouse, Valence, Bourges and elsewhere in the course of his wandering life. He is the outstanding representative of humanism in Roman law. The glossators (*g.r.*) had studied Roman law as it stood at Justinian's death and the commentators (*g.r.*), or Bartolists, had used the comprehensive grasp of Justinian acquired by the glossators as the basis of a systematic science, but as their aim was practical they introduced non-Roman elements into the civil law and adapted it to contemporary needs. The school of Cujas viewed the Roman texts as historical documents, interpreting them in the full setting of ancient history and literature. A consummate master of jurisprudence, philology and history, Cujas may claim to be the greatest legal scholar of all time. He edited a number of unknown texts (Ulpian's *Regular*, the *Consultatio*, parts of Paul's *Sententiae*) and reedited others, notably the Theodosian code. The most famous of his works are his *Observationum et emendationum libri XVI*, published from 1556 to his death except for the last four books, which

were edited after his death by Pithou; and his commentaries upon Papinian, also first published posthumously. The general object of his numerous exegetical works is to restore the fragments of the jurists preserved in Justinian to their original form and meaning. The number and quality of his pupils show how decisive his work was for the historical study of the texts, but it was prejudicial to the practical application of Roman law. In that respect his break with tradition was retrograde, and his adversaries, the Bartolists, rightly retained their hold on practice. In youth Cujas was a Calvinist, but in later life he conformed to Catholicism.

The Promptuarium universorum operum Jacobi Cujacii of Dominicus Albanensis (2 vols., later ed. Naples 1795) is an index to the work of Cujas and gives ready access to the eleven-volume Naples (1722-27) and Venice-Modena (1758-83) reprints of the *Opera omnia* edited by C. A. Fahrot (10 vols., Paris 1658).

Girard, appear in *Revue historique de droit français*, vol. XI (1917) 403-24, and vol. XLV (1920) 243-73.

CULPEPER, SIR THOMAS, the elder (1578-1662), English economist. Culpeper was the author of tracts on trade and the rate of interest. His principal work, *A Tract against the High Rate of Usury* (London 1621), urged that the maximum legal rate, the charging of anything above which constituted a criminal offense, be lowered from the 10 percent sanctioned by the act of 1571 to 6 percent. The tract was presented to the Parliament of 1623-24, of which he was a member, and perhaps contributed to the securing of the passage of a statute reducing the maximum to 8 percent. A third edition appeared in 1641, bound up with an addition under an extension of the same title, written in 1640 and supporting the arguments of the former by reference to the improvements in trade and the rise in land values since the reduction of 1623-24. He now urged the lowering of the rate to 5 or 6 percent. A reduction of the legal rate of interest to

6 percent took place in 1651 and was confirmed in 1660.

In his tracts Culpeper leaves the problem of the unlawfulness of interest to the moralists and confines his discussion to the economic evils of a high interest rate. His arguments show an understanding of the connection of prosperity with the rate of interest and some insight into the nature of interest itself. "The rate of usury is the measure by which all men trade, purchase build, plant, or any ways bargain." "Money hatcheth no eggs of her own; whatsoever is given for use is taken either from the fruits of the land or man's industry." He believed that the mere passage of a law would reduce the interest rate and bring to England the same prosperity as Holland was enjoying under a rate of 3 to 4 percent.

So important did his campaign for a lower interest rate appear to Culpeper that he literally bequeathed it to his son, Sir Thomas Culpeper, the younger (1626-97). In their last conversations the father attempted to convey to his son the spirit and substance of his arguments. In 1668 the younger Culpeper wrote an introductory note to a reprint of his father's pamphlet on usury. In the same year he published his own principal pamphlets on interest, *A Discourse*, on the abatement of usury, and *A Short Appendix to a Late Treatise Concerning Abatement of Usury* (London). Although he wrote with greater fulness than his father he added little to the latter's thesis. Sir Josiah Child's *Brief Observations Concerning Trade* (London 1668) made the same plea as the elder Culpeper's pamphlet published in 1621, which Child appended to his own work.

The almost simultaneous publication of these various arguments for lower interest rates provoked a lively controversy over the causation and effects of high and low market rates for loans. Thomas Manley's boisterous *Usury at Six Percent Examined* (London 1669) and a less able anonymous tract entitled *Interest of Money Mistaken* (London 1668) both argued that Child and Culpeper had inverted cause and effect and that low interest follows and does not precede the healthy development of national industry and resources. Child subsequently gave ground to the opposition, but the younger Culpeper answered with confident assurance in *The Necessity of Abating Usury Re-asserted* (London 1670). Child's book and the appended Culpeper pamphlet were translated into French (Paris 1754) by the physiocrat de Gournay, who was

influenced somewhat by the views of these two Englishmen.

A. V. JUDGES

Consult: Roscher, W., *Zur Geschichte der englischen Volkswirtschaftslehre im 16. und 17. Jahrhundert* (Leipzig 1851) p. 57-58; Rambaud, Joseph, *Histoire des doctrines économiques* (3rd ed. Paris 1909) p. 131; Cassel, G., *The Nature and Necessity of Interest* (London 1903) p. 10-16.

CULTS. Religion as conceived today may be divided into three parts: (1) a description of the world man lives in, especially of its hidden working causes and operative powers, usually in the dramatized forms of gods, angels, devils, ghosts and the like with their characteristic dispositions and more or less symbolic biographies, called myths; (2) an account of the fortunes and destiny of man in this world—his origination, pilgrimage and end, his salvation or damnation; (3) a technique to move and control the operative powers and working causes of the world so that human purposes may be facilitated both in the daily economy of human life and in eternity. The various branches of theology and religious cosmology are embodied in the first of these divisions; the second includes the ethical systems, the characters, the virtues, the vices, the attitudes and ambitions which are prospered or defeated at the hands of the unseen causes and powers; in the third are contained all the observances, the rituals, the liturgies and other devices of address and worship by means of which the unseen powers are set to work upon the accomplishment of desired ends. The relations between these parts are organic; that is, wherever any one is present the other two will also be found; wherever any one is deficient the other two will tend to vary and fail. For this reason formal definitions of religion have been prone to stress one of its three components against the others, the locus of the stress depending on the state of society and its intellectual life at the time. But no religion is whole and healthy without its participation in all three constituents of religion.

The third component of religion is its cultus. It is psychologically perhaps religion's most important organ. For being essentially a mode of behavior it is the nucleus out of which both theologies and ethics are generated and on which they are sustained. It changes last and least of the three aspects of religions, so that secularization consists essentially in the neglect of cultus. There are those indeed who see in cultus the whole substance of religion. The

meaning of religion, they argue, reduces itself to a parcel or collection of practises in relation to the unseen powers or causes, thus to the ways of "getting right with God." All else—theology, ethics, their variations and derivatives—serve simply as verbal extensions, refinements, generalizations, explanations and interpretations of these practises. It is for this reason that in old, unsecularized religions, such as orthodox Judaism or Roman Catholicism, observances and "duties" bulk so large; while in late, secularized ones, such as Unitarianism, the more recent modernistic sects and Ethical Culture, cosmology and ethics bulk large and tend to dissipate into the vague. Even the most secularized religion, however, must retain a minimum of distinctive observance, of particular action and utterance, in which its communicants may join and be as one. Lacking this they could not be a religious society at all.

It may be said then that every religion is a cult, every cult is a religion; that it is the specific form of observance or cultus which distinguishes one religion from another, or within any given religion one sect from another. Cosmology, theology and ethics may be the same; if the rites vary, the religions are different; they are different ways of getting right with God.

The way to be right with the god—or whatever other name may be given to the unseen power on which prosperity and misfortune are believed to depend—is to cultivate him; that is, to assume the attitudes, to perform the acts and to pronounce the words which are pleasing in his sight and which move him therefore to provide in return what man's heart desires. Such cultivation is worship. When it is practised by an organized association or fellowship through the agency of a professional priesthood it is the definitive differentia of a church. Its diffusion depends on a variety of factors. Of these the outstanding are trade and war. Every merchant, sailor and soldier, every traveler or migrant for that matter, is *ipso facto* a culture carrier. Even among unfriendly people his ways are observed and reacted to. Automatically a certain osmosis occurs of customs, attitudes and ideas. Thus the much more highly developed cultures of Egypt, Persia and Syria were disseminated throughout Italy and the western part of the Roman Empire through foreign war, immigration, commerce and slavery. And the tradesmen, the craftsmen, the slaves and the soldiers brought to the West not only the oriental industrial arts but also the oriental

religions. Another factor is direct missionary activity. Ecclesiastical functionaries undertake systematic "selling" of their mysteries in behalf of their own establishments, insisting on the superiority of their techniques of salvation over those of all their competitors. The third agency is force; cults are imposed at the point of the sword, as were in many instances Christianity and Mohammedanism. Still another factor is indoctrination of the young through control of the schools.

The use of the sword and the school, if persisted in long enough, proves effective whether or not the new members of the communion would have joined it had they been let alone. This is not, however, true either of missionary propaganda or of the less direct diffusion by traders, soldiers and slaves. Diffusion of cultus is after all one thing, its adoption another. The infection may be present and yet not take. That it shall take requires a need and a readiness. Potential initiates and prospective converts must feel somehow insecure, somehow defeated. The gods they do serve must be felt as inadequate instruments of salvation beside the competing ones of the newcomer. The new cultus must offer greater present benefits and final satisfactions. Such was the case, as Cumont shows, in the spread of the oriental religions in pagan Rome; such was the case in the rise and survival of Christian variants in Catholic Europe; such is the case wherever men change from one religion to another. The religions of the Great Mother, of Isis and of Mithras, the astrological religions from Syria, displaced the native Roman and Greek religions because of their richer and more varied appeal to eye and ear and heart. Their rituals were more sensuous and colorful, their sacraments (such as the taurobolium) more emotionally impressive and their assurances of security and immortality more dogmatic and incontrovertible. The initiate was made to feel sensibly convinced that he had undergone a purgation and made an expiation which left him with his lost purity restored for this world and his everlasting life guaranteed for the world to come. Against such advantages not even the power of the state could successfully fight. For example, the Phrygian religion of Mâ or Cybele was proscribed at first as contrary to the *mos majorum*. Yet it became an official cultus of the state. This was partly due to its relevance to the neuroathenic temper of the times, partly to its connection with victory in a war and with other dangers overcome. Once it was estab-

lished other cults sought a derivative legality by attaching themselves to it, like the cult of Mithras so popular among soldiers. As a consequence divinities became interchangeable, theologies confused and ethics identical; but so long as the rites remained distinct, the cults retained their separateness. A similar history is presented by the cult of Isis and Osiris. From 59 to 48 B.C. the Roman senate labored to check the spread of the Alexandrian worship; but in the end emperors built temples to Isis; her worshippers owned the one scientific—that is, astrological—cosmology of the time, and life eternal was their own sure heritage. The cults of Jehovah and of Jesus broadly repeat the tale, especially the latter with its techniques of baptism for purification and rebirth and its guaranty of immortality by way of the sacraments. It also absorbs so much from its rivals and competitors that it participates in a consensus concerning theology and ethics, and the mutual resemblances in ritual are so striking that church fathers denounce them as inventions of the devil to mislead and destroy true believers. During the fourth century of the Christian era Roman civilization had reached a religious consensus designed to reconcile the variants, made up of neo-Platonism in theology and cosmology, salvationism in ethics and allegory in interpretative methods.

But it was in the variants—the bodies of observance and practise whose traditional and sacred distinctions make the effective life of religion—that the certainty of salvation resided. It is from them, from the direct experience of initiation and purgation and of communion and rebirth, that the validity and authority of a religion derives. Without the living acknowledgment of the miracle accomplished no religion can hold its communicants. The world being what it is and the human heart what it is, this condition cannot even under the most favorable circumstances continue always and everywhere to obtain. No technique works infallibly; no security survives forever. Hope and necessity, sorrow and fear and anger, shock and boredom, impose a perennial creation of variants within the complexus of the existing religious order or the adoption of novelties from without. This keeps happening in the face of the most ingenious preventive measures an ecclesiastical establishment can apply—slow tortures and fiery deaths. Thus within the complexus of the older Christian cultus are to be found cults of saints, of angels, of sacred relics, of heavenly bodies

and of Satan which challenge and supersede the worship of the authorized Christian gods. Besides such unsanctioned cults there are those which ecclesiastical authority itself adds, like the cult of the Virgin Mary, of newly canonized saints, newly consecrated relics, images and places. Heretics, Protestants and Dissenters also initiate their own variations in the techniques of working on unseen powers so as to assure their intervention in behalf of the heart's desire. The variation may be anything: the use of two rather than three fingers in benediction, of hooks and eyes rather than buttons to fasten Christian garments, of a baptism by total immersion rather than by sprinkling, of ritually washing feet at stated seasons, of a married rather than an unmarried clergy, of a vernacular rather than a sacred tongue like Latin or Hebrew, of congregational rather than episcopal organization, of somber rather than gorgeous sacerdotal dress, of polygamy rather than monogamy, Karezza rather than procreation, and so on.

However small the item of variation it operates as the prime cause in the making of sects, the modification of doctrines and the resuscitation of religious sentiment. Any problem in the life of an individual or a group may serve to initiate a modification of behavior toward unseen power which attracts converts by its emotional congruity and practical promise and which becomes in the course of time the stylized ritual distinguishing a new cult. The various Baptist and Methodist sects, Mormonism, Christian Science, the House of David, Baháism, Russellism, Holy Rollers, Pentecostalism, to mention only a few in an endless catalogue, are all distinguished by their special techniques, ceremonial and societal, of getting right with God. The creators or discoverers of these techniques need not themselves be convinced of them; their purposes may be altogether ulterior and their role may be to themselves that of swindlers and charlatans. This has no bearing on the success or failure of their cults. These depend not at all on the moral character of the founders but on the credited function of the cults among their communicants, on the sense of present security and well-being and the certainty of ultimate salvation which they establish. It is for this reason that the unseen power which the cult tends need not be supernatural only. Any work or ideal of man, any event or quality in nature, any personality enhanced by psychic distance, may become the object of

techniques which cultivate it in the belief that much good accrues from such action to the cultivator. Hence the Browning cults and the Shakespeare cults, the cults of beauty, of health, of atheism, of communism, of the constitution. Hence too the overtone of invidiousness and depreciation which now attaches to the word cult. To say cult is often to imply an upstart or déclassé religion, a worship not quite proper, without the correct sanctions, a pretender religion, suspect to the public opinion of the particular society in which it sets up for business. If it gain in numbers, wealth and power it ceases to be a cult and becomes a religion. Cult, again, is the other fellow's worship, not one's own; Protestants refer to Roman Catholicism as a cult but not to Protestantism; Catholics deny that Protestantism is Christian at all; and agnostics and infidels will decry all religions as cults.

CULTURAL GEOGRAPHY. See GEOGRAPHY.

CULTURE. Man varies in two respects: in physical form and in social heritage, or culture. The science of physical anthropology, employing a complex apparatus of definitions, descriptions and terminologies and somewhat more precise methods than common sense and untutored observation, has succeeded in cataloguing the various branches of mankind according to their bodily structure and physiological characteristics. But man varies also in an entirely different aspect. A pure blooded Negro

infant, transported to France and brought up there, would differ profoundly from what he would have been if reared in the jungle of his native land. He would have been given a different social heritage: a different language, different habits, ideas and beliefs; he would have been incorporated into a different social organization and cultural setting. This social heritage is the key concept of cultural anthropology, the other branch of the comparative study of man. It is usually called culture in modern anthropology and social science. The word culture is at times used synonymously with civilization, but it is better to use the two terms distinctively, reserving civilization for a special aspect of more advanced cultures. Culture comprises inherited artifacts, goods, technical processes, ideas, habits and values. Social organization cannot be really understood except as a part of culture; and all special lines of inquiry referring to human activities, human groupings and human ideas and beliefs can meet and become cross fertilized in the comparative study of cultures.

Man in order to live continually alters his surroundings. On all points of contact with the outer world he creates an artificial, secondary environment. He makes houses or constructs shelters; he prepares his food more or less elaborately, procuring it by means of weapons and implements; he makes roads and uses means of transport. Were man to rely on his anatomical equipment exclusively, he would soon be destroyed or perish from hunger and exposure. Defense, feeding, movement in space, all physiological and spiritual needs, are satisfied indirectly by means of artifacts even in the most primitive modes of human life. The man of nature, the *Naturmensch*, does not exist.

This material outfit of man—his artifacts, his buildings, his sailing craft, his implements and weapons, the liturgical paraphernalia of his magic and religion—are one and all the most obvious and tangible aspects of culture. They define its level and they constitute its effectiveness. The material equipment of culture is not, however, a force in itself. Knowledge is necessary in the production, management and use of artifacts, implements, weapons and other constructions and is essentially connected with mental and moral discipline, of which religion, laws and ethical rules are the ultimate source. The handling and possession of goods imply also the appreciation of their value. The manipulation of implements and the consumption of goods also require cooperation. Common work

and common enjoyment of its results are always based on a definite type of social organization. Thus material culture requires a complement less simple, less easily catalogued or analyzed, consisting of the body of intellectual knowledge, of the system of moral, spiritual and economic values, of social organization and of language. On the other hand, material culture is an indispensable apparatus for the molding or conditioning of each generation of human beings. The secondary environment, the outfit of material culture, is a laboratory in which the reflexes, the impulses, the emotional tendencies of the organism are formed. The hands, arms, legs and eyes are adjusted by the use of implements to the proper technical skill necessary in a culture. The nervous processes are modified so as to yield the whole range of intellectual concepts, emotional types and sentiments which form the body of science, religion and morals prevalent in a community. As an important counterpart to these mental processes there are the modifications in the larynx and tongue which fix some of the crucial concepts and values by associating them with definite sounds. Artifact and custom are equally indispensable and they mutually produce and determine one another.

Language is often regarded as something distinct from both man's material possessions and his system of customs. This view is frequently coupled with a theory by which meaning is regarded as a mystical content of the word, which can be transmitted in utterance from one mind to another. But the meaning of a word is not mysteriously contained in it but is rather an active effect of the sound uttered within a context of situation. The utterance of sound is a significant act indispensable in all forms of human concerted action. It is a type of behavior strictly comparable to the handling of a tool, the wielding of a weapon, the performance of a ritual or the concluding of a contract. The use of words is in all these forms of human activity an indispensable correlate of manual and bodily behavior. The meaning of words consists in what they achieve by concerted action, the indirect handling of the environment through the direct action upon other organisms. Speech therefore is a bodily habit and is comparable to any other type of custom. The learning of language consists in the development of a system of conditioned reflexes which at the same time become conditioned stimuli. Speech is the production of articulate sounds, developed in childhood out of the inarticulate infantile utter-

ances which constitute the child's main endowment in dealing with his environment. As the individual grows his increase of linguistic knowledge runs parallel with his general development. A growing knowledge of technical processes is bound up with the learning of technical terms; the development of his tribal citizenship and social responsibility is accompanied by the acquisition of a sociological vocabulary and of polite speech, commands and legal phraseology; the growing experience of religions and moral values is associated with the development of ritual and ethical formulae. The full knowledge of language is the inevitable correlate of the full attainment of a tribal and cultural status. Language thus is an integral part of culture; it is not, however, a system of tools but rather a body of vocal customs.

Social organization is often regarded by sociologists as remaining outside culture, but the organization of social groups is a complex combination of material equipment and bodily customs which cannot be divorced from either its material or psychological substratum. Social organization is the standardized manner in which groups behave. But a social group consists always of individuals. The child, attached to its parents through the satisfaction of all its needs, grows up within the shelter of the parental house, hut or tent. The domestic hearth is the center around which the various necessities of warmth, comfort, food and companionship are satisfied. Later in every human society communal life is associated with the local settlement, the town, village or compound; it is localized within definite boundaries and associated with private and public activities of an economic, political and religious nature. In every organized activity therefore human beings are bound together by their connection with a definite portion of environment, by their association with a common shelter and by the fact that they carry out certain tasks in common. The concerted character of their behavior is the result of social rules, that is, customs, either sanctioned by explicit measures or working in an apparently automatic way. The sanctioned rules—laws, customs and manners—belong to the category of acquired bodily habits. The essence of moral values by which man is driven to definite behavior by inner compulsion has in religious and metaphysical thought been ascribed to conscience, the will of God or an inborn categorical imperative; while some sociologists have explained it as due to a supreme moral being—

society, or the collective soul. Moral motivation when viewed empirically consists in a disposition of the nervous system and of the whole organism to follow within given circumstances a line of behavior dictated by inner constraint which is due neither to innate impulses nor yet to obvious gains or utilities. The inner constraint is the result of the gradual training of the organism within a definite set of cultural conditions. The impulses, desires and ideas are within each society welded into specific systems, in psychology called sentiments. Such sentiments define the attitudes of a man toward the members of his group, above all his nearest kindred; toward the material objects of his surroundings; toward the country which he inhabits; toward the community with which he works; toward the realities of his magical, religious or metaphysical *Weltanschauung*. Fixed values or sentiments often condition human behavior so that man prefers death to surrender or compromise, pain to pleasure, abstention to satisfaction of desire. The formation of sentiments and thus of values is always based on the cultural apparatus in a society. Sentiments are formed over a long space of time and through a very gradual training or conditioning of the organism. They are based on forms of organization, very often world wide, such as the Christian church, the community of Islam, the empire, the flag—all symbols or catchwords, behind which, however, there exist vast and living cultural realities.

The understanding of culture is to be found in the process of its production by succeeding generations and in the way in which it produces in each new generation the appropriately molded organism. The metaphysical concepts of a group mind, collective sensorium or consciousness are due to an apparent antinomy of sociological reality: the psychological nature of human culture on the one hand and on the other the fact that culture transcends the individual. The fallacious solution of this antinomy is the theory that human minds combine or integrate and form a superindividual and yet essentially spiritual being. Durkheim's theory of moral constraint by the direct influence of the social being, the theories based on a collective unconscious and archetype of culture, such concepts as consciousness of kind or the inevitability of collective imitation, account for the psychological yet superindividual nature of social reality by introducing some theoretical metaphysical short cut.

The psychological nature of social reality is, however, due to the fact that its ultimate me-

dium is always the individual mind or nervous system. The collective elements are due to the sameness of reaction within the small groups which act as units of social organization by the process of conditioning and to the medium of material culture within which the conditioning takes place. The small groups which act as units because of their mental sameness are then integrated into the larger schemes of social organization by the principles of territorial distribution, cooperation and division into strata of material culture. Thus the reality of the superindividual consists in the body of material culture, which remains outside any individual and yet influences him in the ordinary physiological manner. There is nothing mystical therefore in the fact that culture is at the same time psychological and collective.

Culture is a reality *sui generis* and must be studied as such. The various sociologies which treat the subject matter of culture by way of the organic simile or in the likeness of a collective mind are irrelevant. Culture is a well organized unity divided into two fundamental aspects—a body of artifacts and a system of customs—but also obviously into further subdivisions or units. The analysis of culture into its component element, the relation of these elements to one another and their relation to the needs of the human organism, to the environment and to the universally acknowledged human ends which they subserve are important problems of anthropology.

Anthropology has dealt with its material by two different methods, controlled by two incompatible conceptions of the growth and history of culture. The evolutionary school has regarded the growth of culture as a series of spontaneous metamorphoses proceeding according to definite laws and producing a fixed sequence of successive stages. This school took for granted the divisibility of culture into simple elements and it treated these elements as if they were units of the same order; it presented theories of the evolution of fire making side by side with accounts of how religion developed, versions of the origin and development of marriage and doctrines as to the development of pottery. Stages of economic development and steps in the evolution of domestic animals, of cutting implements and of ornamental design were formulated. Yet there is no doubt that, although certain implements have changed, passed through a sequence of stages and obeyed more or less definite laws of evolution, the

family, marriage or religious beliefs are not subject to any simple, dramatic metamorphoses. The fundamental institutions of human culture have changed not by way of sensational transformations but rather through an increasing differentiation of form in accordance with an increasingly definite function. Until the nature of the various cultural phenomena, their function and their form are understood and described more fully, it seems premature to speculate on possible origins and stages. The concepts of origins, stages, laws of development and growth of culture have remained nebulous and essentially non-empirical. The method of evolutionary anthropology was based primarily on the concept of survival, since this allowed the student to reconstruct past stages from present day conditions. The concept of survival, however, implies that a cultural arrangement can outlive its function. The better a certain type of culture is known, the fewer survivals there appear to be in it. Evolutionary inquiry should therefore be preceded by a functional analysis of culture.

The same criticism applies to the historical or diffusionist school, which attempts to reconstruct the history of human cultures mainly by tracing their diffusion. This school denies the importance of spontaneous evolution and maintains that cultures have been produced mainly by the imitation or taking over of artifacts and customs. The method of the school consists in a careful mapping out of cultural similarities over large portions of the globe and in speculative reconstructions as to how the similar units of culture have wandered from one place to another. The disputes of historical anthropologists (for there is little consensus between Elliot Smith and F. Boas; W. J. Perry and Pater Schmidt; Clark Wissler and Graebner; or Frobenius and Rivers) refer mostly to the questions as to where a type of culture originated, whether it moved and how it was transported. The difference is primarily due to the way in which each school conceives, on the one hand, the divisions of culture into its component parts and, on the other, the process of diffusion. This process has been very little studied in its present day manifestations, and it is only from the empirical study of contemporary diffusion that an answer can be found as to its past history. The method of division of culture into its component units, which are then supposed to diffuse, is even less satisfactory. The concepts of cultural traits, trait complexes and *Kultur-*

komplexe are indiscriminately applied to single utensils or implements, such as the boomerang, the bow or the fire drill, or to vague characteristics of material culture, such as megalithicity, sexual suggestiveness of the cowrie shell or certain details of objective form. Agriculture, the worship of fertility and enormous yet vague principles of social grouping, such as dual organization, the clan system or a type of religious cult, are regarded as single traits, that is, units of diffusion. But culture cannot be regarded as a fortuitous agglomerate of such traits. Only elements of the same order can be treated as identical units of argument; only compatible elements compound into a homogeneous whole. Insignificant details of material culture, on the one hand, social institutions and cultural values, on the other, must be treated differently. They are not invented in the same way, cannot be carried, diffused or implanted in the same manner.

The weakest point in the method of the historical school is the way in which its members establish the identity of cultural elements. For the whole problem of historical diffusion is raised by the occurrence of really or apparently identical traits or complexes in different areas. In order to establish the identity of two elements of culture the diffusionist uses the criteria of what might be called irrelevant form and fortuitous concatenation of elements respectively. The irrelevance of form is a fundamental concept because form, which is dictated by inner necessity, could have developed independently. Complexes, naturally concatenated, could also be the product of independent evolution—hence the need to consider only fortuitously connected traits. Accidental concatenation, however, and irrelevant detail of form can, according to Graebner and his followers, be only the result of direct diffusion. But irrelevance of form and fortuitousness of concatenation are both negative assertions, which in the last instance mean that the form of an artifact or an institution cannot be accounted for or the concatenation between several elements of culture found. The historical method uses absence of knowledge as its basis of argument. To be valid its results must be preceded by a functional study of the given culture, which should exhaust all the possibilities of explaining form by function and of establishing relationships between the various elements of culture.

If culture in its material aspect is primarily a body of instrumental artifacts, it seems at first sight improbable that any culture should harbor

a great many irrelevant traits, survivals or fortuitous complexes either dumped down by some itinerant alien culture or handed over as survivals, useless fragments of a vanished stage. Still less is it likely that customs, institutions or moral values should present this necrotic or irrelevant character in which the evolutionary and diffusionist schools are primarily interested.

Culture consists of the body of commodities and instruments as well as of customs and bodily or mental habits which work directly or indirectly for the satisfaction of human needs. All the elements of culture, if this conception be true, must be at work, functioning, active, efficient. The essentially dynamic character of cultural elements and of their relations suggests that it is in the study of cultural function that the most important task of anthropology consists. The primary concern of functional anthropology is with the function of institutions, customs, implements and ideas. It holds that the cultural process is subject to laws and that the laws are to be found in the function of the real elements of culture. The atomizing or isolating treatment of cultural traits is regarded as sterile, because the significance of culture consists in the relation between its elements, and the existence of accidental or fortuitous culture complexes is not admitted.

To formulate a number of fundamental principles an example may be taken from material culture. The simplest artifact, extensively used in the simplest cultures, a plain stick, roughly trimmed, some five to six feet long, such as can be used for digging up roots or in the cultivation of the soil, for punting or in walking, is an ideal element or trait of culture for it has a fixed, simple form, is apparently a self-contained unit and is very important in every culture. To define the cultural identity of a stick by its form, by describing its material, its length, its weight, its color or any other physical characteristics by describing it in fact according to the final criterion of form as it is used by the diffusionist—would be a methodically erroneous procedure. The digging stick is handled in its own way; it is used in a garden or in the bush for a special purpose; it is procured and discarded in a somewhat careless manner for a single specimen has usually very small economic value. But the digging stick looms large in the economic scheme of every community in which it is used as well as in folklore, mythology and customs. A stick of identical form can be used in the same culture as a punting pole, a walking staff or a rudimentary

weapon. But in each of these specific uses the stick is embedded in a different cultural context; that is, put to different uses, surrounded with different ideas, given a different cultural value and as a rule designated by a different name. In each case it forms an integral part of a different system of standardized human activities. In brief, it fulfils a different function. It is the diversity of function not the identity of form that is relevant to the student of culture. The stick exists as a part of culture only in so far as it is used in human activities, in so far as it serves human needs; and therefore the digging stick, the walking staff, the punting pole, although they may be identical in physical nature, are each a distinct element of culture. For the simplest as well as the most elaborate artifact is defined by its function, the part which it plays within a system of human activities; it is defined by the ideas which are connected with it and by the values which surround it.

This conclusion receives its importance from the fact that the systems of activities to which material objects are referred are not fortuitous but are organized, well determined, comparable systems found throughout the world of cultural diversity. The cultural context of the digging stick, the system of agricultural activities, always presents the following component parts: a portion of territory is legally set aside for the use of a human group by the rules of land tenure. A body of traditional usages exists regulating the way in which this territory is to be cultivated. Technical rules, ceremonial and ritual usages determine in every culture what plants are to be grown; how the ground is to be cleared, the soil prepared and fertilized; how the work is to proceed; how, when and by whom the magical acts or religious ceremonies are to be performed; how, finally, the crops are to be harvested, distributed, stored and consumed. Likewise the group of people who own the territory, the plant and the produce, who work together, enjoy and consume the results of their labors, are always well defined.

These are the characteristics of the institution of gardening as it is universally found wherever the environment is favorable to the cultivation of the soil and the level of culture sufficiently high to allow it. The fundamental identity of this organized system of activities is due primarily to the fact that it is built up around the satisfaction of a deep human need—the regular provision of staple food of a vegetable nature. The satisfaction of this need by agriculture,

which insures possibility of control, regularity of production and relative abundance, is so superior to any other food providing activity that it was bound to diffuse or to develop wherever conditions were favorable and the level of culture sufficiently high.

The fundamental uniformity in institutionalized gardening is due to yet another cause, the principle of limited possibilities, first laid down by Goldenweiser. Given a definite cultural need, the means of its satisfaction are small in number, and therefore the cultural arrangement which comes into being in response to the need is determined within narrow limits. Given the human need for a support, a rudimentary weapon and an implement for exploring in the dark, the material most suitable is wood, the only adequate shape thin and long, and a plentiful supply is accessible. Yet a sociology or cultural theory of the walking staff is possible, for the staff displays a diversity of uses, ideas and mystical associations and in its ornamental, ritual and symbolic developments becomes a part of important institutions such as magic, chieftainship and kingship.

The real component units of cultures which have a considerable degree of permanence, universality and independence are the organized systems of human activities called institutions. Every institution centers around a fundamental need, permanently unites a group of people in a cooperative task and has its particular body of doctrine and its technique of craft. Institutions are not correlated simply and directly to their functions: one need does not receive one satisfaction in one institution. But institutions show a pronounced amalgamation of functions and have a synthetic character. The local or territorial principle and relationship by procreation act as the most important integrative factors. Every institution is based on a material substratum of apportioned environment and of cultural apparatus.

To define cultural identity of any artifact is possible only by placing it within the cultural context of an institution, by showing how it functions culturally. A pointed stick, that is, a spear, used as a hunting weapon leads to the study of the type of hunting, as practised in a given culture, in which it functions, the legal rights of hunting, the organization of the team, the technique, the magical ritual, the distribution of the quarry, as well as the relation of the particular type of hunting to other types and the general importance of hunting within the econ-

omy of the tribe. Canoes have often been taken as characteristic traits for the establishment of cultural affinities and hence as a proof of diffusion because the form varies within a wide range and shows types of outstanding character, such as the canoe with single or double outrigger, the balsa, the kayak, the catamaran or the double canoe. And yet this complex artifact cannot be defined by form alone. The canoe, to the people who produce, possess, use and value it, is primarily a means to an end. They have to cross an expanse of water either because they live on small islands or in pile dwellings; or because they want to trade or have to fish or go to war; or because of the desire for exploration and adventure. The material object, the sailing craft, its form, its peculiarities, are determined by the special use to which it is put. Every use dictates a special system of sailing, that is, in the first place, the technique of using paddles, the steering oar, the mast, the rigging or the sail. Such techniques, however, are invariably based on knowledge: principles of stability, buoyancy, conditions of speed and response to steering. The form and structure of the canoe are closely related to the technique and manner of its use. Yet innumerable accounts of the mere form and structure of a canoe are available, while little is known about the technique of sailing and the relation of this to the particular use to which a canoe is put.

The canoe has also its sociology. Even when manned by a single person it is owned, produced, lent or hired, and in this the group as well as the individual is invariably implicated. But usually the canoe has to be handled by a crew and this entails the complex sociology of ownership, of division of functions, of rights and obligations. These are rendered more complex by the fact that a large vessel has to be produced communally, and production and ownership are usually related. All these facts, which are complex but regulated, which show several aspects, all of which are related according to definite rules, determine the form of the canoe. Form cannot be treated as a self-contained independent trait, accidental and irrelevant, diffusing alone without its context. All the assumptions, arguments and conclusions which concern the diffusion of an element and the spread of culture in general will have to be modified once it is acknowledged that what diffuse are institutions and not traits, forms or fortuitous complexes.

In the construction of seagoing craft there are certain stable elements of form determined by

the nature of the activity to which the craft is instrumental. There are certain variable elements due either to alternative possibilities of solution or else to less relevant details associated with any possible solution. This is a universal principle referring to all artifacts. The commodities used for the direct satisfaction of bodily needs or consumed in use must fulfil conditions laid down by the direct bodily need. Foodstuffs, for instance, are within certain limits determined by physiology; they must be nourishing, digestible, non-poisonous. They are of course also determined by environment and by the level of culture. Habitations, clothing, shelter, fire as source of warmth, light and dryness, weapons, sailing craft and roads are within limits determined by the bodily needs to which they are correlated. Implements, tools or machines which are used for the production of commodities have their nature and form defined by the purpose for which they are to be used. Cutting or scraping, joining or smashing, striking or driving, piercing or drilling, define the form of an object within narrow limits.

But variations occur within the limits imposed by the primary function, which causes the primary characters of an artifact to remain stable. There is no indefinite variation, but a fixed type occurs as if a choice had been made and then adhered to. In any seafaring community, for instance, there is not found an infinite variety of craft ranging from a simple hollowed log to a complicated outrigger; at most a few forms occur, differentiated by size and construction and also by social setting and purpose, and each traditional form is reproduced constantly to the smallest detail of decoration and constructive process.

Anthropology has so far concentrated its attention on these secondary regularities of form which cannot be accounted for by the primary function of the object. The regular occurrence of such apparently accidental details of form has raised the question whether they are due to independent invention or diffusion. But many such details are to be explained by the cultural context; that is, the special way in which an object is used by a man or a group of people, by the ideas, rites and ceremonial associations which surround its primary use. The ornamentation of a walking staff usually means that it has received within a culture a ceremonial or religious association. A digging stick may be weighted, sharply pointed or blunt, according to the character of the soil, the plants grown and

the type of cultivation. The explanation of the South Sea outrigger may be found in the fact that this arrangement gives the greatest stability, seaworthiness and manageability, considering the limitations in material and in technical handicraft of the Oceanic cultures.

The form of cultural objects is determined by direct bodily needs on the one hand and by instrumental uses on the other, but this division of needs and uses is neither complete nor satisfactory. The ceremonial staff used as a mark of rank or office is neither a tool nor a commodity, and customs, words and beliefs cannot be referred either to physiology or to the workshop.

Man like any animal must receive nourishment, and he has to propagate if he is to continue individually and racially. He must also have permanent safeguards against dangers coming from the physical environment, from animals or from other human beings. A whole range of necessary bodily comforts must be provided - shelter, warmth, a dry lair and means of cleanliness. The effective satisfaction of these primary bodily needs imposes or dictates to every culture a number of fundamental aspects; institutions for nutrition, or the commissariat; institutions for mating and propagation; and organizations for defense and comfort. The organic needs of man form the basic imperatives leading to the development of culture in that they compel every community to carry on a number of organized activities. Religion or magic, the maintenance of law or systems of knowledge and mythology occur with such persistent regularity in every culture that it must be assumed that they also are the result of some deep needs or imperatives.

The cultural mode of satisfaction of the biological needs of the human organism creates new conditions and thus imposes new cultural imperatives. With insignificant exceptions, desire for food does not bring man directly in touch with nature and force him to consume the fruits as they grow in the forest. In all cultures, however simple, staple food is prepared and cooked and eaten according to strict rules within a definite group and with the observance of manners, rights and tabus. It is usually obtained by more or less complicated, collectively carried out processes, such as agriculture, exchange or some system of social cooperation and communal distribution. In all this man is dependent on the artificially produced apparatus of weapons, agricultural implements, fishing craft and tackle. He is equally dependent upon organ-

ized cooperation and upon economic and moral values.

Thus out of the satisfaction of physiological needs there grow derived imperatives. Since they are essentially means to an end they may be called the instrumental imperatives of culture. These are as indispensable to man's commissariat, to the satisfaction of his nutritive needs, as the raw material of food and the processes of its ingestion. For man is so molded that if he were deprived of his economic organization and of his implements he would as effectively starve as if the substance of his foodstuffs were withdrawn from him.

From the biological point of view the continuity of race might be satisfied in a very simple manner: it would be enough for people to mate, to produce two or occasionally more children per couple, enough to insure that two individuals survive for every two who die. If biology alone controlled human procreation, people would mate by rules of physiology which are the same for the whole species; they would produce offspring in the natural course of pregnancy and childbirth; and the animal species man would have its typical family life, physiologically defined. The human family, the biological unit, would then present exactly the same constitution throughout humanity. It would also remain outside the scope of cultural science—as has been in fact postulated by many sociologists, notably by Durkheim. But instead, mating, that is, the system of courtship, love making and selection of consorts, is in every human society traditionally defined by the body of cultural customs prevalent in that community. There are rules which debar some people from marriage and make it desirable if not compulsory for others to marry; there are rules of chastity and rules of license; there are strictly cultural elements which blend with the natural impulse and produce an ideal of attractiveness which varies from one society and one culture to another. In place of a biologically determined uniformity a bewildering variety of sexual customs and courtship arrangements regulating mating exist. Marriage within each human culture is by no means a simple sexual union or even cohabitation of two people. It is invariably a legal contract defining the mode in which man and wife should live together and the economic conditions of their union, such as cooperation in property, mutual contributions and contributions of the respective relatives of either consort. It is invariably a public ceremony, a matter for

social concern, involving large groups of people as well as the two main actors. Its dissolution as well as its conclusion is subject to fixed traditional rules.

Nor is parenthood a mere biological relationship. Conception is the subject of a rich traditional folklore in every human community and has its legal side in the rules which discriminate between children conceived in wedlock and out of it. Pregnancy is surrounded by an atmosphere of moral values and rules. Usually the expectant mother is compelled to lead a special mode of life hedged in by tabus, all of which she has to observe on account of the welfare of the child. There is thus a culturally established, anticipatory maternity which foreshadows the biological fact. Childbirth is also an event deeply modified by ritual, legal, magical and religious concomitants, in which the emotions of the mother, her relations to the child and the relations of both to the social group are molded so as to conform to a specific traditional pattern. The father also is never passive or indifferent at childbirth. Tradition closely defines the parental duties during early pregnancy and the manner in which they are divided between husband and wife and partly shifted to more distant relatives.

Kinship, the tie between the child and its parents and their relatives, is never a haphazard affair. Its development is determined by the legal system of the community, which organizes on a definite pattern all emotional responses as well as all duties, moral attitudes and customary obligations. The important distinction between matrilineal and patrilineal relatives, the development of the wider or classificatory kinship relations as well as the formation of clans, or sibs, in which large groups of relatives are to a certain extent regarded and treated as real kindred, are cultural modifications of natural kinship. Procreation thus becomes in human societies a vast cultural scheme. The racial need of continuity is not satisfied by the mere action of physiological impulses and physiological processes but by the working of traditional rules associated with an apparatus of material culture. The procreative scheme, moreover, is seen to be composed of several component institutions: standardized courtship, marriage, parenthood, kinship and clanship. In the same way the nutritive scheme may be divided into the consuming institutions, that is, household or clubhouse with its men's refectory; the productive institutions, of tribal gardening, hunting and fishing; and the distributive institutions, such as markets and trad-

ing arrangements. Impulses act in the form of social or cultural commands, which are the re-interpretations of physiological drives in terms of social, traditionally sanctioned rules. The human being starts to court or to dig the soil, to make love or to go hunting or fishing, not because he is directly moved by an instinct but because the routine of his tribe makes him do these things. At the same time tribal routine insures that physiological needs are satisfied and that the cultural means of satisfaction conform to the same pattern with only minor variations in detail. The direct motive for human actions is couched in cultural terms and conforms to a cultural pattern. But cultural commands always bid man to satisfy his needs in a more or less direct manner, and on the whole the system of cultural commands in a given society leaves but few of the physiological needs unsatisfied.

An amalgamation of functions occurs in most human institutions. The household is not merely a reproductive institution: it is one of the main nutritive institutions and an economic, legal and often a religious unit. The family is the place where cultural continuity through education is served. This amalgamation of functions within the same institution is not fortuitous. Most of man's fundamental needs are so concatenated that their satisfaction can be best provided for within the same human group and by a combined apparatus of material culture. Even human physiology causes birth to be followed by lactation, and this is inevitably associated with the tender cares of the mother for the child, which gradually shade into the earliest educational services. The mother requires a male helpmate, and the parental group must become a cooperative as well as an educational association. The fact that marriage is an economic as well as an educational and procreative relation influences courtship deeply, and this becomes a selection for lifelong companionship, common work and common responsibilities, so that sex must be blended with other personal and cultural requirements.

Education means training in the use of implements and goods, in the knowledge of tradition, in the wielding of social power and responsibility. The parents who develop in their offspring economic attitudes, technical dexterities, moral and social duties, have also to hand over their possessions, their status or their office. The domestic relationship therefore implies a system of laws of inheritance, descent and succession.

The relation between the cultural need, an

integral social fact, on the one hand, and, on the other, the individual motives into which it becomes translated is thus clarified. The cultural need is the body of conditions which must be fulfilled if the community is to survive and its culture to continue. The individual motives, on the other hand, have nothing to do with such postulates as the continuity of race or the continuity of culture or even the need of nutrition. Few people, savage or civilized, realize that such general necessities exist. The savage is ignorant or only very vaguely conscious of the fact that mating produces children and that eating sustains the body. What is present to an individual consciousness is a culturally shaped appetite which impels people at certain seasons to look for a mate or in certain circumstances to look for wild fruit, to dig the ground or to go fishing. Sociological aims are never present in the minds of natives, and tribal legislation on a large scale could never have occurred. A theory, for instance, such as that of Frazer concerning the origins of exogamy in a deliberate act of primeval law giving is untenable. Throughout anthropological literature there is a confusion between cultural needs, which find their expression in vast schemes or aspects of social constitution, and conscious motivation, which exists as a psychological fact in the mind of an individual member of a society.

Custom, a standardized mode of behavior traditionally enjoined on the members of a community, can act or function. Courtship, for example, is really but one stage in the process of culturally defined procreation. It is the body of arrangements which allow of an adequate choice in marriage. Since the contract of marriage varies considerably from one culture to another, the consideration of sexual, legal and economic adequacy also varies, and the mechanisms by which these various elements are blended cannot be the same. However great may be the sexual liberty allowed, in no human society are young people permitted to be entirely indiscriminate or promiscuous in experimental love making. Three main types of limitation are known: the prohibition of incest, respect for previous matrimonial obligations and the rules of combined exogamy and endogamy. The prohibition of incest is with a few insignificant exceptions universal. If incest could be proved to be biologically pernicious, the function of this universal tabu would be obvious. But specialists in heredity disagree on the subject. It is possible, however, to show that from a

sociological point of view the function of incest tabus is of the greatest importance. The sexual impulse, which is in general a very upsetting and socially disruptive force, cannot enter into a previously existing sentiment without producing a revolutionary change in it. Sexual interest is therefore incompatible with any family relationship, whether parental or between brothers and sisters, for these relations are built up in the presexual period of human life and are founded on deep physiological needs of a non-sexual character. If erotic passion were allowed to invade the precincts of the home it would not merely establish jealousies and competitive elements and disorganize the family but it would also subvert the most fundamental bonds of kinship on which the further development of all social relations is based. Only one erotic relationship can be allowed within each family, and that is the relation between the husband and wife, which although it is built from the outset on erotic elements must be very finely adjusted to the other component parts of domestic co-operation. A society which allowed incest could not develop a stable family; it would therefore be deprived of the strongest foundations for kinship, and this in a primitive community would mean absence of social order.

Exogamy eliminates sex from a whole set of social relations, those between clansmen and clanswomen. Since the clan forms the typical cooperative group, the members of which are united by a number of legal, ceremonial and economic interests and activities, exogamy by dissociating the disruptive and competitive element from workaday cooperation fulfils once more an important cultural function. The general safeguarding of sexual exclusiveness in matrimony establishes that relative stability of marriage which again is inevitable if this institution is not to be undermined by the jealousies and suspicions of competitive wooing. The fact that none of the rules of incest, exogamy and adultery ever work with absolute precision and automatic force only enhances the cogency of this argument, for it is the elimination of the open working of sex which is most important. The surreptitious evasion of the rules and their occasional overriding on ceremonial occasions function as safety vents and reactions against their often irksome stringency.

Traditional rules define the season for love making, the methods of approach and wooing, even the means of attracting and pleasing. Tradition also allows of definite liberties and

even excesses, although it also sets rigorous limits to them. These limits define the degree of publicity, of promiscuity, of verbal and active indecencies; they define what is to be regarded as normal and what as perverse. In all this the real drives of human behavior in sex do not consist of natural physiological impulses but reach human consciousness in the form of commands dictated by tradition. The powerful disruptive influence of sex has to be given free play within limits. The main type of regulated liberty is the free choice of mating left to unmarried people, which has often been wrongly regarded as a survival of primitive promiscuity. To appreciate the function of prenuptial laxity it must be correlated with biological facts, with the institution of marriage and with the parental life within the household. The sexual impulse which leads people to mate is overwhelmingly more powerful than any other motive. Where marriage is the indispensable condition to sexual mating this impulse overriding all other considerations may lead to unions which are neither spiritually nor physiologically adequate or stable. In higher cultures a moral training and a subordination of sex to wider cultural interests function as general safeguards against an exclusive dominance of the erotic element in marriage, or else culturally determined marriages arranged by parents or families assert the influence of economic and cultural factors over mere eroticism. In certain primitive communities as well as among large portions of European peasantry, 'mating' as a means of assessing personal compatibility and to a large extent also as the means of eliminating mere sexual urge functions as a safeguard to the institution of permanent marriage. Through prenuptial liberties in the course of courtship people cease to value the mere lure of erotic attractiveness and, on the other hand, they become more and more influenced by personal affinities, if there is no physiological incompatibility. The function then of prenuptial liberty is that it influences the matrimonial choice, which becomes deliberate, based on experience and directed by wider and more synthetic considerations than the blind impulse of sex. Prenuptial unchastity therefore functions as a mode of preparation for marriage in eliminating the crude, non-empirical, untutored sex impulse and in welding this impulse with others into a deeper appreciation of personality.

The couvade, the symbolic ritual by which a man imitates childbed while his wife goes about

her work, is also not a survival but can be explained functionally in its cultural context.

In the ideas, customs and social arrangements which refer to conception, pregnancy and childbirth the fact of maternity is culturally determined over and above its biological nature. Paternity is established in a symmetrical way by rules in which the father has partly to imitate the tabus, observances and rules of conduct traditionally imposed on the mother and has also to take over certain associated functions. The behavior of the father at childbirth is strictly defined, and everywhere, whether he be excluded from the mother's company or forced to assist, whether he be regarded as dangerous or indispensable to the welfare of the mother and child, the father has to assume a definite, strictly prescribed role. Later the father shares a great many of the mother's duties; he follows and replaces her in a great many of the tender cares bestowed on the infant. The function of *couvade* is the establishment of social paternity by the symbolic assimilation of the father to the mother. Far from being a dead or useless survival or trait *couvade* is merely one of the creative ritual acts at the basis of the institution of the family. Its nature can be understood not by isolating it, not by emphasizing its strangeness and tearing it out of its natural setting, but, on the contrary, only by placing it within the institutions to which it belongs, by comprehending it as an integral part of the institution of the family.

Classificatory terminologies are conceived as having at one time embodied some "intelligent plan" (as Morgan put it) for the classification of relatives. In Morgan's theory this classification was supposed to have given with an almost mathematical precision the limits of potential paternity. According to more recent theories, notably that of Rivers, classificatory terminologies were once the clear and real expression of anomalous marriages. Whatever the concrete turn of the various theories the fact of classificatory terminologies has been the source of a flood of speculations about the sequence of stages in the evolution of marriage, about anomalous unions, about primitive gerontocracy and promiscuity, about the clan or some other communal procreative scheme taking at one stage or another the place of the family. Few, however, seriously inquired into the present day function of classificatory terms. McLennan suggested that they might be a mere polite mode of address, and in this he was followed by a few

writers. But since these nomenclatures are very rigidly adhered to and since, as Rivers has shown, they are associated with definite social status, McLennan's explanation has had to be discarded.

Classificatory terminologies, however, fulfil a very important and a very specific function, which can only be appreciated on the basis of a careful study of how the terms develop meaning during the life history of the tribesman. The first meaning acquired by the child is always individual. It is based on personal relations to the father and mother, to brothers and sisters. A full outfit of family terms with well determined individual meaning is always acquired before any further linguistic developments. But then a series of extensions of meaning takes place. The words mother and father come to be applied first to the mother's sister and father's brother respectively, but they are applied to these people in a frankly metaphorical manner; that is, with an extended and different meaning which in no way interferes with or obliterates the original meaning when this is applied to the original parents. The extension takes place because the nearest of kin are in a primitive society under an obligation to act as substitute parents, to replace the child's progenitors in case of death or failure and in all cases to share their duties to a considerable extent. Unless and until complete adoption takes place the substitute parents do not replace the original ones, and in no case are the two sets lumped or identified. They are merely partially assimilated. The naming of people is always a semilegal act, especially in primitive communities. As in ceremonies of adoption there is the imitation of an actual birth, as in the *couvade* there is simulated childbed, as in the act of blood brotherhood there are such fictions as exchange of blood, as in marriage a symbolic binding, tying, joining or act of common eating and common public appearance often takes place—so here a partially established, derived relationship is characterized by the act of verbal imitation in naming. The function of classificatory verbal usage is then the establishment of legal claims of vicarious parenthood by the binding metaphor of extension in kinship terms. The discovery of the function of classificatory terminology opens a set of new problems: the study of the initial situation of kinship, of the extensions of kinship meaning, of the partial taking over of kinship duties and of the changes produced in previous relationships by such extensions. These are empirical problems

leading not to more speculation but to a fuller study of facts in the field. At the same time, the discovery of a function of the use of classificatory terminology in terms of present day sociological reality cuts the ground from under the whole series of speculations by which savage nomenclatures have been explained as survivals of past stages of human marriage.

The apparatus of domesticity influences the moral or spiritual aspect of family life. Its material substratum consists of the dwellings, the internal arrangements, the cooking apparatus and the domestic implements and also of the mode of settlement; that is, of the manner in which the dwellings are distributed over the territory. This material substratum enters most subtly into the texture of family life and influences deeply its legal, economic and moral aspects. The constitution of a household characteristic of a culture becomes deeply associated with the material side of the interior of the dwelling, whether it be a skyscraper or a wind screen, a sumptuous apartment or a hovel. There is an infinite range of intimate personal associations with it from infancy and childhood, through the time of puberty and emotional awakening, into the stage of courtship and early married life, until old age. The sentimental and romantic implications of these facts are acknowledged in contemporary culture, in the preserving and cultivating of the birthplaces and homes of famous men. But although a great deal is known about the technology of house building and even about the structure of houses in various cultures and although a fair amount is also known about the constitution of the family, few accounts deal with the relation between the form of the dwelling and the form of domestic arrangements, on the one hand, and the constitution of the family, on the other, and yet such a relation does exist. The isolated homestead distant from all others makes for a strongly knit, self-contained, economically as well as morally independent family. Self-contained houses collected into village communities allow of a much closer texture in derived kinship and greater extent of local cooperation. Houses compounded into joint households, especially when they are united under one owner, are the necessary basis of a joint family or *Grossfamilie*. Large communal houses where only a separate hearth or partition distinguishes the various component families make for a yet more closely knit system of kinship. Finally, the existence of special club-houses, where the men, the bachelors or the un-

married girls of a community sleep, eat or cook together, is obviously correlated to the general structure of a community when kinship is complicated by age grades, secret societies and other male or female associations and is usually also correlated to the presence or absence of sexual laxity.

The further the correlation between sociology and the form of settlement and dwelling is followed, the better either side is understood. While on the one hand the form of material arrangements receives its only significance from its sociological context, on the other hand the whole objective determination of social and moral phenomena can best be defined and described in terms of the material substratum as it molds and influences the social and spiritual life of a culture. The arrangements within the house also show the need of a parallel study and correlation of the material and spiritual. The meager furniture, the hearth, the sleeping bunks, the mats and pegs of a native hut, show a simplicity, even poverty, of form, which, however, becomes immensely significant through the depth and the range of sociological and spiritual association. The hearth, for instance, varies but little in form: a few indications as to how the stones are placed, how the smoke is carried off, how supports for cooking are arranged, how the fire is used for warming and for lighting the interior, are sufficient from the mere technical side. But even in stating these simple details one is led into the study of typical uses of fire, into the indication of human attitudes and emotions; in short, into the analysis of the social and moral customs which form round the hearth. For the hearth is the center of domestic life; and the manner in which it is used, the customs of kindling, keeping and extinguishing, the domestic cult which often develops round it, the mythology and the symbolic significance of the hearth, are indispensable data for the study of domesticity and of its place in culture. In the Trobriand Islands, for instance, the hearth has to be placed in the center, lest sorcery, which is mainly effective through the medium of smoke, should be carried in from outside. The hearth is the special property of women. Cooking is to a certain extent tabu to men and its proximity pollutes uncooked vegetable food. Hence there is a division between storerooms and cooking houses in the villages. All this makes the simple material arrangements of a house a social, moral, legal and religious reality.

The disposition of sleeping bunks is likewise

correlated with the sexual and parental side of married life, with incest tabus and the need for unmarried peoples' houses; the access to a house is correlated with the seclusion of family life, with property and sexual morality. Everywhere form becomes more and more significant the better the relation of sociological realities and their material substratum is understood. Ideas, customs and laws codify and determine material arrangements, while these latter are the main apparatus for molding every new generation into the typical traditional pattern of its society.

The primary biological needs of a community, that is, the conditions under which a culture can thrive, develop and continue, are satisfied in an indirect manner which imposes secondary or derived conditions. These may be designated as the instrumental imperatives of culture. The whole body of material culture must be produced, maintained, distributed and used. In every culture therefore a system of traditional rules or commands is found which defines the activities, usages and values by which food is produced, stored and apportioned, goods manufactured, owned and used, tools prepared and embodied in production. An economic organization is indispensable to every community, and culture must always keep in touch with its material substratum.

Regulated cooperation exists even in such simple activities as the search for food among the lowest primitives. They at times have to apportion big tribal gatherings, and this requires a complicated system of commissariat. Within the family there is a division of labor, and the cooperation of families within the local community is never a simple economic matter. The maintenance of the utilitarian principle in production is closely related to artistic, magical, religious and ceremonial activities. Primitive property in land, in personal possession and in the various means of production is far more complex than older anthropology assumed, and the study of primitive economics is developing a considerable interest in what might be called the early forms of civil law.

Cooperation means sacrifice, effort, subordination of private interests and inclinations to the joint ends of the community, the existence of social constraint. Life in common offers various temptations, especially to the impulses of sex, and as a result a system of prohibitions and restraints as well as of mandatory rules is unavoidable. Economic production provides man with things desirable and valuable, not un-

restrictedly accessible for use and enjoyment to everybody alike, and rules of property, of possession and use are developed and enforced. Special organization entails differences in rank, leadership, status and influence. Hierarchy develops social ambitions and requires safeguards, which are effectively sanctioned. This whole set of problems has been signally neglected because law and its sanctions are in primitive communities very rarely embodied in special institutions. Legislation, legal sanctions and effective administration of tribal rules are very often carried out as by-products of other activities. The maintenance of law is usually one of the secondary or derived functions of such institutions as the family, the household, the local community and the tribal organization. But although not laid down in a specific body of codified rules nor yet carried out by specially organized groups of people the sanctions of primitive law function none the less in a special manner and develop special features in the institutions to which they belong. For it is essentially incorrect to maintain, as has often been done, that primitive law works automatically and that the savage is naturally a law abiding citizen. Rules of conduct must be drilled into each new generation through education; that is, provision must be made for the continuity of culture through the instrumentality of tradition. The first requisite is the existence of symbolic signs in which condensed experience can be handed over from one generation to another. Language is the most important type of such symbolic signs. Language does not contain experience; it is rather a system of sound habits which accompanies the development of cultural experience in every human community and becomes an integral part of this cultural experience. In primitive cultures tradition remains oral. The speech of a primitive tribe is full of set sayings, maxims, rules and reflections, which in a stereotyped manner carry on the wisdom of one generation into another. Folk tales and mythology form another department of verbal tradition. In higher cultures writing is added to carry on spoken tradition. The failure to realize that language is an integral part of culture has led to the vague, metaphorical and misleading parallels between animal societies and human culture which have done much harm to sociology. If it were clearly realized that culture without language does not exist, the treatment of animal communities would cease to be a part of sociology and animal adaptations to nature would be clearly dis-

tinguished from culture. Education in primitive society seldom commands specific institutions. The family, the group of extended kindred, the local community, age grades, secret societies, initiation camps, the professional groups or guilds of technical, magical or religious craft—these are the institutions which correspond in some of their derived functions to schools in more advanced cultures.

The three instrumental imperatives, economic organization, law and education, do not exhaust all that culture entails in its indirect satisfaction of human needs. Magic and religion, knowledge and art, are part of the universal scheme which underlies all concrete cultures and may be said to arise in response to an integrative or synthetic imperative of human culture.

In spite of the various theories about a specific non-empirical and prelogical character of primitive mentality there can be no doubt that as soon as man developed the mastery of environment by the use of implements, and as soon as language came into being, there must also have existed primitive knowledge of an essentially scientific character. No culture could survive if its arts and crafts, its weapons and economic pursuits were based on mystical, non-empirical conceptions and doctrines. When human culture is approached from the pragmatic, technological side, it is found that primitive man is capable of exact observation, of sound generalizations and of logical reasoning in all those matters which affect his normal activities and are at the basis of his production. Knowledge is then an absolute derived necessity of culture. It is more, however, than a means to an end, and it was not classed therefore with the instrumental imperatives. Its place in culture, its function, is slightly different from that of production, of law or of education. Systems of knowledge serve to connect various types of behavior; they carry over the results of past experiences into future enterprise and they bring together elements of human experience and allow man to coordinate and integrate his activities. Knowledge is a mental attitude, a diathesis of the nervous system, which allows man to carry on the work which culture makes him do. Its function is to organize and integrate the indispensable activities of culture.

The material embodiment of knowledge consists in the body of arts and crafts, of technical processes and rules of craftsmanship. More specifically, in most primitive cultures and certainly in higher ones there are special imple-

ments of knowledge—diagrams, topographical models, measures, aids to orientation or to counting.

The connection between native thought and language opens important problems of function. Linguistic abstraction, categories of space, time and relationship and logical means of expressing the concatenation of ideas are extremely important matters, and the study of how thought works through language in any culture is still a virgin field of cultural linguistics. How primitive language works, where it is embodied, how it is related to social organization, to primitive religion and magic, are important problems of functional anthropology.

By the very forethought and foresight which it gives, the integrative function of knowledge creates new needs, that is, imposes new imperatives. Knowledge gives man the possibility of planning ahead, of embracing vast spaces of time and distance; it allows a wide range to his hopes and desires. But however much knowledge and science help man in allowing him to obtain what he wants they are unable completely to control chance, to eliminate accidents, to foresee the unexpected turn of natural events or to make human handiwork reliable and adequate to all practical requirements. In this field, much more practical, definite and circumscribed than that of religion, there develops a special type of ritual activities which anthropology labels collectively as magic.

The most hazardous of all human enterprises known to primitive man is sailing. In the preparation of his sailing craft and the laying out of his plans the savage turns to his science. The painstaking work as well as the intelligently organized labor in construction and in navigation bears witness to the savage's trust in science and submission to it. But adverse wind or no wind at all, rough weather, currents and reefs are always liable to upset his best plans and most careful preparations. He must admit that neither his knowledge nor his most painstaking efforts are a guaranty of success. Something unaccountable usually enters and baffles his anticipations. But although unaccountable it yet appears to have a deep meaning, to act or behave with a purpose. The sequence, the significant concatenation of events, seems to contain some inner logical consistency. Man feels that he can do something to wrestle with that mysterious element or force, to help and abet his luck. There are therefore always systems of superstition, of more or less developed ritual, associated with sailing, and in

primitive communities the magic of sailing craft is highly developed. Those who are well acquainted with some good magic have, in virtue of that, courage and confidence. When the canoes are used for fishing, the accidents and the good or bad luck may refer not only to transport but also to the appearance of fish and to the conditions under which they are caught. In trading, whether overseas or with near neighbors, chance may favor or thwart the ends and desires of man. As a result both fishing and trading magic are very well developed.

Likewise in war man, however primitive, knows that well made weapons of attack and defense, strategy, the force of numbers and the strength of the individuals insure victory. Yet with all this the unforeseen and accidental help even the weaker to victory when the fray happens under the cover of night, when ambushes are possible, when the conditions of the encounter obviously favor one side at the expense of the other. Magic is used as something which over and above man's equipment and his force helps him to master accident and to ensnare luck. In love also a mysterious, unaccountable quality of success or else a predestination to failure seems to be accompanied by some force independent of ostensible attraction and of the best laid plans and arrangements. Magic enters to insure something which counts over and above the visible and accountable qualifications.

Primitive man depends on his economic pursuits for his welfare in a manner which makes him realize bad luck very painfully and directly. Among people who rely on their fields or gardens what might be called agricultural knowledge is invariably well developed. The natives know the properties of the soil, the need of a thorough clearing from brush and weed, fertilizing with ashes and appropriate planting. But however well chosen the site and well worked the gardens, mishaps occur. Drought or deluge coming at most inappropriate seasons destroys the crops altogether, or some blights, insects or wild animals diminish them. Or some other year, when man is conscious that he deserves but a poor crop, everything runs so smoothly and prosperously that an unexpectedly good return rewards the undeserving gardener. The dreaded elements of rain and sunshine, pests and fertility seem to be controlled by a force which is beyond ordinary human experience and knowledge, and man repairs once more to magic.

In all these examples the same factors are in-

volved. Experience and logic teach man that within definite limits knowledge is supreme; but beyond them nothing can be done by rationally founded practical exertions. Yet he rebels against inaction because although he realizes his impotence he is yet driven to action by intense desire and strong emotions. Nor is inaction at all possible. Once he has embarked on a distant voyage or finds himself in the middle of a fray or halfway through the cycle of garden growing, the native tries to make his frail canoe more seaworthy by charms or to drive away locusts and wild animals by ritual or to vanquish his enemies by dancing.

Magic changes its forms; it shifts its ground; but it exists everywhere. In modern societies magic is associated with the third cigarette lit by the same match, with spilled salt and the need of throwing it over the left shoulder, with broken mirrors, with passing under a ladder, with the new moon seen through glass or on the left hand, with the number thirteen or with Friday. These are minor superstitions which seem merely to vegetate among the intelligentsia of the western world. But these superstitions and much more developed systems also persist tenaciously and are given serious consideration among modern urban populations. Black magic is practised in the slums of London by the classical method of destroying the picture of the enemy. At marriage ceremonies good luck for the married couple is obtained by the strictest observance of several magical methods such as the throwing of the slipper and the spilling of rice. Among the peasants of central and eastern Europe elaborate magic still flourishes and children are treated by witches and warlocks. People are thought to have the power to prevent cows from giving milk, to induce cattle to multiply unduly, to produce rain and sunshine and to make people love or hate each other. The saints of the Roman Catholic church become in popular practise passive accomplices of magic. They are beaten, cajoled and carried about. They can give rain by being placed in the fields, stop flows of lava by confronting them and stop the progress of a disease, of a blight or of a plague of insects. The crude practical use made of certain religious rituals or objects makes their function magical. For magic is distinguished from religion in that the latter creates values and attains ends directly, whereas magic consists of acts which have a practical utilitarian value and are effective only as a means to an end. Thus a strictly utilitarian subject matter or issue of an act and its direct, instru-

mental function make it magic, and most modern established religions harbor within their ritual and even their ethics a good deal which really belongs to magic. But modern magic not only survives in the forms of minor superstitions or within the body of religious systems. Wherever there is danger, uncertainty, great incidence of chance and accident, even in entirely modern forms of enterprise, magic crops up. The gambler at Monte Carlo, on the turf or in a continental state lottery develops systems. Motoring and modern sailing demand mascots and develop superstitions. Around every sensational sea tragedy there has formed a myth showing some mysterious magical indications or giving magical reasons for the catastrophe. Aviation is developing its superstitions and magic. Many pilots refuse to take up a passenger who is wearing anything green, to start a journey on a Friday or to light three cigarettes with a match when in the air, and their sensitiveness to superstition seems to increase with altitude. In all large cities of Europe and America magic can be purchased from palmists, clairvoyants and other soothsayers who forecast the future, give practical advice as to lucky conduct and retail ritual apparatus such as amulets, mascots and talismans. The richest domain of magic, however, is, in civilization as in savagery, that of health. Here again the old venerable religions lend themselves readily to magic. Roman Catholicism opens its sacred shrines and places of worship to the ailing pilgrim, and faith healing flourishes also in other churches. The main function of Christian Science is the thinking away of illness and decay; its metaphysics are very strongly pragmatic and utilitarian and its ritual is essentially a means to the end of health and happiness. The unlimited range of universal remedies and blessings, osteopathy and chiropractic, dietetics and curing by sun, cold water, grape or lemon juice, raw food, starvation, alcohol or its prohibition—one and all shade invariably into magic. Intellectuals still submit to Coué and Freud, to Jaeger and Kneipp, to sun worship, either direct or through the mercury vapor lamp—not to mention the bedside manner of the highly paid specialist. It is very difficult to discover where common sense ends and where magic begins.

The savage is not more rational than modern man nor is he more superstitious. He is more limited, less liable to free imaginings and to the confidence trick of new inventions. His magic is traditional and he has his stronghold of knowledge, his empirical and rational tradition of

science. Since the superstitious or prelogical character of primitive man has been so much emphasized, it is necessary to draw clearly the dividing line between primitive science and magic. There are domains on which magic never encroaches. The making of fire, basketry, the actual production of stone implements, the making of strings or mats, cooking and all minor domestic activities although extremely important are never associated with magic. Some of them become the center of religious practises and of mythology, as, for example, fire or cooking or stone implements; but magic is never connected with their production. The reason is that ordinary skill guided by sound knowledge is sufficient to set man on the right path and to give him certainty of correct and complete control of these activities.

In some pursuits magic is used under certain conditions and is absent under others. In a maritime community depending on the products of the sea there is never magic connected with the collecting of shellfish or with fishing by poison, weirs and fish traps, so long as these are completely reliable. On the other hand, any dangerous, hazardous and uncertain type of fishing is surrounded by ritual. In hunting the simple and reliable ways of trapping or killing are controlled by knowledge and skill alone; but let there be any danger or any uncertainty connected with an important supply of game and magic immediately appears. Coastal sailing as long as it is perfectly safe and easy commands no magic. Overseas expeditions are invariably bound up with ceremonies and ritual. Man resorts to magic only where chance and circumstances are not fully controlled by knowledge.

This is best seen in what might be called systems of magic. Magic may be but loosely and capriciously connected with its practical setting. One hunter may use certain formulae and rites, and another ignore them; or the same man may apply his conjurings on one occasion and not on another. But there are forms of enterprise in which magic must be used. In a big tribal adventure, such as war, or a hazardous sailing expedition or seasonal travel or an undertaking such as a big hunt or a perilous fishing expedition or the normal round of gardening, which as a rule is vital to the whole community, magic is often obligatory. It runs in a fixed sequence concatenated with the practical events, and the two orders, magical and practical, depend on one another and form a system. Such systems of magic appear at first sight an inextricable mix-

ture of efficient work and superstitious practises and so seem to provide an unanswerable argument in favor of the theories that magic and science are under primitive conditions so fused as not to be separable. Fuller analysis, however, shows that magic and practical work are entirely independent and never fuse.

But magic is never used to replace work. In gardening the digging or the clearing of the ground or the strength of the fences or quality of the supports is never scamped because stronger magic has been used over them. The native knows well that mechanical construction must be produced by human labor according to strict rules of craft. He knows that all the processes which have been in the soil can be controlled by human effort to a certain extent but not beyond, and it is only this beyond which he tries to influence by magic. For his experience and his reason tell him that in certain matters his efforts and his intelligence are of no avail whatever. On the other hand, magic has been known to help; so at least his tradition tells him.

In the magic of war and of love, of trading expeditions and of fishing, of sailing and of canoe making, the rules of experience and logic are likewise strictly adhered to as regards technique, and knowledge and technique receive due credit in all the good results which can be attributed to them. It is only the unaccountable results, which an outside observer would attribute to luck, to the knack of doing things successfully, to chance or to fortune, that the savage attempts to control by magic.

Magic therefore, far from being primitive science, is the outgrowth of clear recognition that science has its limits and that a human mind and human skill are at times impotent. For all its appearances of megalomania, for all that it seems to be the declaration of the "omnipotence of thought," as it has recently been defined by Freud, magic has greater affinity with an emotional outburst, with daydreaming, with strong, unrealizable desire.

To affirm with Frazer that magic is a pseudo-science would be to recognize that magic is not really primitive science. It would imply that magic has an affinity with science or at least that it is the raw material out of which science develops—implications which are untenable. The ritual of magic shows certain striking characteristics which have made it quite plausible for most writers from Grimm and Tylor to Freud and Lévy-Bruhl to affirm that magic takes the place of primitive science.

Magic unquestionably is dominated by the sympathetic principle: like produces like; the whole is affected if the sorcerer acts on a part of it; occult influences can be imparted by contagion. If one concentrates on the form of the ritual only he can legitimately conclude with Frazer that the analogy between the magical and the scientific conceptions of the world is close and that the various cases of sympathetic magic are mistaken applications of one or the other of two great fundamental laws of thought, namely, the association of ideas by similarity and the association of ideas by contiguity in space or time.

But a study of the function of science and the function of magic casts a doubt on the sufficiency of these conclusions. Sympathy is not the basis of pragmatic science, even under the most primitive conditions. The savage knows scientifically that a small pointed stick of hard wood rubbed or drilled against a piece of soft, brittle wood, provided they are both dry, gives fire. He also knows that strong, energetic, increasingly swift motion has to be employed, that tinder must be produced in the action, the wind kept off and the spark fanned immediately into a glow and this into a flame. There is no sympathy, no similarity, no taking the part instead of the legitimate whole, no contagion. The only association or connection is the empirical, correctly observed and correctly framed concatenation of natural events. The savage knows that a strong bow well handled releases a swift arrow, that a broad beam makes for stability and a light, well shaped hull for swiftness in his canoe. There is here no association of ideas by similarity or contagion or *pars pro toto*. The native puts a yam or a banana sprout into an appropriate piece of ground. He waters or irrigates it unless it be well drenched by rain. He weeds the ground round it, and he knows quite well that barring unexpected calamities the plant will grow. Again there is no principle akin to that of sympathy contained in this activity. He creates conditions which are perfectly scientific and rational and lets nature do its work. Therefore in so far as magic consists in the enactment of sympathy, in so far as it is governed by an association of ideas, it radically differs from science; and on analysis the similarity of form between magic and science is revealed as merely apparent, not real.

The sympathetic rite although a very prominent element in magic functions always in the context of other elements. Its main purpose always consists in the generation and transference

of magical force and accordingly it is performed in the atmosphere of the supernatural. As Hubert and Mauss have shown, acts of magic are always set apart, regarded as different, conceived and carried out under distinct conditions. The time when magic is performed is often determined by tradition rather than by the sympathetic principle, and the place where it is performed is only partly determined by sympathy or contagion and more by supernatural and mythological associations. Many of the substances used in magic are largely sympathetic but they are often used primarily for the physiological and emotional reaction which they elicit in man. The dramatic emotional elements in ritual enactment incorporate, in magic, factors which go far beyond sympathy or any scientific or pseudo-scientific principle. Mythology and tradition are everywhere embedded, especially in the performance of the magical spell, which must be repeated with absolute faithfulness to the traditional original and during which mythological events are recounted in which the power of the prototype is invoked. The supernatural character of magic is also expressed in the abnormal character of the magician and by the temporary tabus which surround its execution.

In brief, there exists a sympathetic principle: the ritual of magic contains usually some reference to the results to be achieved; it foreshadows them, anticipates the desired events. The magician is haunted by imagery, by symbolism, by associations of the result to follow. But he is quite as definitely haunted by the emotional obsession of the situation which has forced him to resort to magic. These facts do not fit into the simple scheme of sympathy conceived as misapplication of crude observations and half logical deductions. The various apparently disjointed elements of magical ritual, the dramatic features, the emotional side, the mythological allusions and the anticipation of the end - make it impossible to consider magic a sober scientific practise based on an empirical theory. Nor can magic be guided by experience and at the same time be constantly harking back to myth.

The fixed time, the determined spot, the preliminary isolating conditions of magic, the tabus to be observed by the performer, as well as his physiological and sociological nature, place the magical act in an atmosphere of the supernatural. Within this context of the supernatural the rite consists, functionally speaking, in the production of a specific virtue or force and of the

launching, directing or impelling of this force to the desired object. The production of magical force takes place by spell, manual and bodily gesticulation and the proper condition of the officiating magician. All these elements exhibit a tendency to a formal assimilation toward the desired end or toward the ordinary means of producing this end. This formal resemblance is probably best defined in the statement that the whole ritual is dominated by the emotions of hate, fear, anger or erotic passion or by the desire to obtain a definite practical end.

The magical force or virtue is not conceived as a natural force. Hence the theories propounded by Preuss, Marett, Hubert and Mauss, which would make the Melanesian mana or the similar North American concepts the clue to the understanding of all magic, are not satisfactory. The mana concept embraces personal power, natural force, excellence and efficiency alongside the specific virtue of magic. It is a force regarded as absolutely *sui generis*, different either from natural forces or from the normal faculties of man.

The force of magic can be produced only and exclusively within traditionally prescribed rites. It can be received and learned only by due initiation into the craft and by the taking over of the rigidly defined system of conditions, acts and observances. Even when magic is discovered or invented it is invariably conceived as true revelation from the supernatural. Magic is an intrinsic, specific quality of a situation and of an object or phenomenon within the situation, consisting in the object being amenable to human control by means which are specifically and uniquely connected with the object and which can be handled only by appropriate people. Magic therefore is always conceived as something which does not reside in nature, that is, outside man, but in the relation between man and nature. Only those objects and forces in nature which are very important to man, on which he depends and which he cannot yet normally control elicit magic.

A functional explanation of magic may be stated in terms of individual psychology and of the cultural and social value of magic. Magic is to be expected and generally to be found whenever man comes to an unbridgeable gap, a hiatus in his knowledge or in his powers of practical control, and yet has to continue in his pursuit. Forsaken by his knowledge, baffled by the results of his experience, unable to apply any effective technical skill, he realizes his impo-

tence. Yet his desire grips him only the more strongly. His fears and hopes, his general anxiety, produce a state of unstable equilibrium in his organism, by which he is driven to some sort of vicarious activity. In the natural human reaction to frustrated hate and impotent anger is found the *materia prima* of black magic. Unrequited love provokes spontaneous acts of prototype magic. Fear moves every human being to aimless but compulsory acts; in the presence of an ordeal one always has recourse to obsessive daydreaming.

The natural flow of ideas under the influence of emotions and desires thwarted in their full practical satisfaction leads one inevitably to the anticipation of the positive results. But the experience upon which this anticipatory or sympathetic attitude rests is not the ordinary experience of science. It is much more akin to daydreaming, to what the psychoanalysts call wish fulfillment. When the emotional state reaches the breaking point at which man loses control over himself, the words which he utters, the gestures to which he gives way and the physiological processes within his organism which accompany all this allow the pent up tension to flow over. Over all such outbursts of emotion, over such acts of prototype magic, there presides the obsessive image of the desired end. The substitute action in which the physiological crisis finds its expression has a subjective value: the desired end seems nearer satisfaction.

Standardized, traditional magic is nothing else but an institution which fixes, organizes and imposes upon the members of a society the positive solution in those inevitable conflicts which arise out of human impotence in dealing with all hazardous issues by mere knowledge and technical ability. The spontaneous, natural reaction of man to such situations supplies the raw material of magic. This raw material implies the sympathetic principle in that man has to dwell both on the desired end and on the best means of obtaining it. The expression of emotions in verbal utterances, in gestures, in an almost mystical belief that such words and gestures have a power, crops up naturally as a normal, physiological reaction. The elements which do not exist in the *materia prima* of magic but are to be found in the developed systems are the traditional, mythological elements. Human culture everywhere integrates a raw material of human interests and pursuits into standardized, traditional customs. In all human tradition a definite choice is made from within a variety of possi-

bilities. In magic also the raw material supplies a number of possible ways of behavior. Tradition chooses from among them, fixes a special type and endues it with a hallmark of social value.

Tradition also reinforces the belief in magical efficacy by the context of special experience. Magic is so deeply believed in because its pragmatic truth is vouched for by its psychological or even physiological efficacy, since in its form and in its ideology and structure magic corresponds to the natural processes of the human organism. The conviction which is implied in these processes extends obviously to standardized magic. This conviction is useful because it raises the efficiency of the person who submits to it. Magic possesses therefore a functional truth or a pragmatic truth, since it arises always under conditions where the human organism is disintegrated. Magic corresponds to a real physiological need.

The seal of social approval given to the standardized reactions, selected traditionally out of the raw material of magic, gives it an additional backing. The general conviction that this and only this rite, spell or personal preparation enables the magician to control chance makes every individual believe in it through the ordinary mechanism of molding or conditioning. The public enactment of certain ceremonies, on the one hand, and the secrecy and esoteric atmosphere in which others are shrouded add again to their credibility. The fact also that magic usually is associated with intelligence and strong personality raises its credit in the eyes of any community. Thus a conviction that man can control by a special, traditional, standardized handling the forces of nature and human beings is not merely subjectively true through its physiological foundations, not merely pragmatically true in that it contributes to the reintegration of the individual, but it carries an additional evidence due to its sociological function.

Magic serves not only as an integrative force to the individual but also as an organizing force to society. The fact that the magician by the nature of his secret and esoteric lore has also the control of the associated practical activities causes him usually to be a person of the greatest importance in the community. The discovery of this was one of the great contributions of Frazer to anthropology. Magic, however, is of social importance not only because it gives power and thus raises a man to a high position. It is a real organizing force. In Australia the constitution of the tribe, of the clan, of the local group, is based

on a system of totemic ideas. The main ceremonial expression of this system consists in the rites of magical multiplication of plants and animals and in the ceremonies of initiation into manhood. Both of these rites underlie the tribal framework and they are both the expression of a magical order of ideas based on totemic mythology. The leaders who arrange the tribal meetings, who conduct them, who direct the initiation and are the protagonists in dramatic representations of myth and in the public magical ceremonies, play this part because of their traditional magical filiation. The totemic magic of these tribes is their main organizing system.

To a large extent this is also true of the Papuan tribes of New Guinea, of the Melaneans and of the people of the Indonesian archipelagoes, where magical rites and ideas definitely supply the organizing principle in practical activities. The secret societies of the Bismarck Archipelago and west Africa, the rain makers of the Sudan, the medicine men of the North American Indians— all combine magical power with political and economic influence. Sufficient details to assess the extent and the mechanism by which magic enters and controls secular and ordinary life are often lacking. But among the Masai or Nandi in east Africa the evidence reveals that the military organization of the tribe is associated with war magic and that the guidance in political affairs and general tribal concerns depends on rain magic. In New Guinea garden magic, overseas trading expeditions, fishing and hunting on a big scale show that the ceremonial significance of magic supplies the moral and legal framework by which all practical activities are held together.

Sorcery in its major forms is usually specialized and institutionalized; that is, either the sorcerer is a professional whose services can be bought or commanded or sorcery is vested in a secret society or special organization. In all cases sorcery is either in the same hands as political power, prestige and wealth or else it can be purchased or demanded by those who can afford to do so. Sorcery thus is invariably a conservative force used at times for intimidation but usually for the enforcement of customary law or of the wishes of those in power. It is always a safeguard for the vested interests, for the organized, established privileges. The sorcerer who has behind him the chief or a powerful secret society can make his art felt more poignantly than if he were working against them or on his own.

The individual and sociological function of magic is thus made more efficient by the very mechanisms through which it works. In this and in the subjective aspect of the calculus of probability, which makes success overshadow failure, while failure again can be explained by counter-magic, it is clear that the belief is not so ill founded nor due to such extravagant superstitiousness of the primitive mind as might at first appear. A strong belief in magic finds its public expression in the running mythology of magical miracles which is always found in company with all important types of magic. The competitive boasting of one community against another, the fame of outstanding magical success, the conviction that extraordinary good luck has probably been due to magic, create an ever nascent tradition which always surrounds famous magicians or famous systems of magic with a halo of supernatural reputation. This running tradition usually culminates retrospectively in a primeval myth, which gives the charter and credentials to the whole magical system. Myth of magic is definitely a warrant of its truth, a pedigree of its filiation, a charter of its claims to validity.

This is true not only of magical mythology. Myth in general is not an idle speculation about the origins of things or institutions. Nor is it the outcome of the contemplation of nature and rhapsodical interpretation of its laws. The function of myth is neither explanatory nor symbolic. It is the statement of an extraordinary event, the occurrence of which once for all had established the social order of a tribe or some of its economic pursuits, its arts and crafts or its religious or magical beliefs and ceremonies. Myth is not simply a piece of attractive fiction which is kept alive by the literary interest in the story. It is a statement of primeval reality which lives in the institutions and pursuits of a community. It justifies by precedent the existing order and it supplies a retrospective pattern of moral values, of sociological discriminations and burdens and of magical belief. In this consists its main cultural function. For all its similarity of form myth is neither a mere tale or prototype of literature or of science nor a branch of art or history nor an explanatory pseudo-theory. It fulfils a function *sui generis* closely connected with the nature of tradition and belief, with the continuity of culture, with the relation between age and youth and with the human attitude toward the past. The function of myth is to strengthen tradition and to endow it with a

greater value and prestige by tracing it back to a higher, better, more supernatural and more effective reality of initial events.

The place of religion must be considered in the scheme of culture as a complex satisfaction of highly derived needs. The various theories of religion ascribe it to either a religious "instinct" or a specific religious sense (McDougall, Hauer) or else explain it as a primitive theory of animism (Tylor) or pre-animism (Maret) or ascribe it to the emotions of fear (Wundt) or to aesthetic raptures and lapses of speech (Max Müller) or the self-revelation of society (Durkheim). These theories make religion something superimposed on the whole structure of human culture, satisfying some needs perhaps, but needs which are entirely autonomous and have nothing to do with the hard worked reality of human existence. Religion, however, can be shown to be intrinsically although indirectly connected with man's fundamental, that is, biological, needs. Like magic it comes from the curse of forethought and imagination, which fall on man once he rises above brute animal nature. Here there enter even wider issues of personal and social integration than those arising out of the practical necessity of hazardous action and dangerous enterprise. A whole range of anxieties, forebodings and problems concerning human destinies and man's place in the universe opens up once man begins to act in common not only with his fellow citizens but also with the past and future generations. Religion is not born out of speculation or reflection, still less out of illusion or misapprehension, but rather out of the real tragedies of human life, out of the conflict between human plans and realities.

Culture entails deep changes in man's personality; among other things it makes man surrender some of his self-love and self-seeking. For human relations do not rest merely or even mainly on constraint coming from without. Men can only work with and for one another by the moral forces which grow out of personal attachments and loyalties. These are primarily formed in the processes of parenthood and kinship but become inevitably widened and enriched. The love of parents for children and of children for their parents, that between husband and wife and between brothers and sisters, serve as prototypes and also as a nucleus for the loyalties of clanship, of neighborly feeling and of tribal citizenship. Cooperation and mutual assistance are based, in savage and civilized societies, on permanent sentiments.

The existence of strong personal attachments and the fact of death, which of all human events is the most upsetting and disorganizing to man's calculations, are perhaps the main sources of religious belief. The affirmation that death is not real, that man has a soul and that this is immortal arises out of a deep need to deny personal destruction, a need which is not a psychological instinct but is determined by culture, by cooperation and by the growth of human sentiments. To the individual who faces death the belief in immortality and the ritual of extreme unction, or last comforts (which in one form or another is almost universal), confirm his hope that there is a hereafter, that it is perhaps not worse than the present life and may be better. Thus the ritual before death confirms the emotional outlook which a dying man has come to need in his supreme conflict. After death the bereaved are thrown into a chaos of emotion, which might become dangerous to each of them individually and to the community as a whole were it not for the ritual of mortuary duties. The religious rites of wake and burial—all the assistance given to the departed soul—are acts expressing the dogma of continuity after death and of communion between dead and living. Any survivor who has gone through a number of mortuary ceremonials for others becomes prepared for his own death. The belief in immortality, which he has lived through ritually and practised in the case of his mother or father, of his brothers and friends, makes him cherish more firmly the belief in his own future life. The belief in human immortality therefore, which is the foundation of ancestor worship, of domestic cults, of mortuary ritual and of animism, grows out of the constitution of human society.

Most of the other forms of religion when analyzed in their functional character correspond to deep although derived needs of the individual and of the community. Totemism, for example, when related to its wider setting affirms the existence of an intimate kinship between man and his surrounding world. The ritual side of totemism and nature worship consists to a large extent in rites of multiplication or of propitiation of animals or in rites of enhancing the fertility of vegetable nature which also establish links between man and his environment. Primitive religion is largely concerned with the sacralization of the crises of human life. Conception, birth, puberty, marriage, as well as the supreme crisis death, all give rise to sacramental acts. The fact of conception is sur-

rounded by such beliefs as that in reincarnation, spirit entry and magical impregnation. At birth a wealth of animistic ideas concerning the formation of the human soul, the value of the individual to his community, the development of his moral powers, the possibility of forecasting his fate, become associated with and expressed in birth ritual. Initiation ceremonies, prevalent in puberty, have a developed mythological and dogmatic context. Guardian spirits, tutelary divinities, culture heroes or a tribal All-Father are associated with initiation ceremonies. The contractual sacraments, such as marriage, entry into an age grade or acceptance into a magical or religious fraternity, entail primarily ethical views but very often are also the expression of myths and dogmas.

Every important crisis of human life implies a strong emotional upheaval, mental conflict and possible disintegration. The hopes of a favorable issue have to struggle with anxieties and forebodings. Religious belief consists in the traditional standardization of the positive side in the mental conflict and therefore satisfies a definite individual need arising out of the psychological concomitants of social organization. On the other hand, religious belief and ritual by making the critical acts and the social contracts of human life public, traditionally standardized and subject to supernatural sanctions strengthen the bonds of human cohesion.

Religion in its ethics sanctifies human life and conduct and becomes perhaps the most powerful force of social control. In its dogmatics it supplies man with strong cohesive forces. It grows out of every culture, because knowledge which gives foresight fails to overcome fate; because lifelong bonds of cooperation and mutual interest create sentiments, and sentiments rebel against death and dissolution. The cultural call for religion is highly derived and indirect but is finally rooted in the way in which the primary needs of man are satisfied in culture.

Plays, games, sports and artistic pastimes tear man out of his ordinary rut and remove the strain and the discipline of workaday life, fulfilling the function of recreation, of restoring man to full capacity of routine work. The function of art and play is, however, more complicated and more comprehensive, as may be shown by an analysis of its part in culture. The free untrammelled exercise of infancy is neither play nor game: it combines both. The biological needs of the organism demand that the infant shall employ his limbs and his lungs, and this

free exercise supplies his earliest training as well as his real adaptation to his surroundings. Through his voice the infant appeals to his parents or guardians and thus enters into relation to his society and through this to the world at large. Even these activities, however, do not remain completely free and controlled by physiology only. Every culture determines the latitude which may be given to the freedom of muscular movement—from the swaddled or bound child which can hardly move to the complete liberty of the naked infant. Culture also defines the limits within which the child is allowed to cry and scream and dictates the promptness of parental response and the severity of customary repression. The degree to which earliest behavior is molded, the manner in which words and acts are woven into infantile expression, allow tradition to influence the young organism through its human surroundings. The earliest phases of human play, which is also human work, are therefore of considerable importance, and they must be studied not merely in the behaviorist's laboratory or the psychoanalyst's consulting room but also in the ethnographic field, since they vary with every culture.

The plays and exercise of the next stage, when the child learns to speak and to use his arms and legs, link up directly with the earliest pastimes. The importance of childish playful behavior consists in its relation to the educational influences contained in it, the cooperation with others and with other children. Later the child becomes independent of his parents or guardians to the extent that he joins other children and plays with them. Often the children form a special community having its own rudimentary organization, leadership and economic interests—a community which at times provides its own nourishment—and in complete independence spend days and nights away from the parental homes. At times boys and girls play in separate groups; or again they join in one group, in which case eroticism and sexual interests may or may not enter into the play. The games are usually either in imitation of the adults or contain some parallel activities. They are very seldom completely different from the things in which the child will be engaged after maturity. Thus a great deal of the future adaptation to life is learned in this period. The moral code is developed, the salient features of the character are formed and the friendships or loves of future life are started. This period often contains a partial weaning from family life. It ends in the

ceremonies of initiation into manhood and often at that time begins the formation of wider bonds of clanship, of age grades, secret societies and tribal citizenship. The main function of juvenile play is therefore educational, while the recreative side is practically non-existent as long as and to the extent that the young people do not take part in the regular work of the community.

The plays and recreations of adults usually present a continuous development from those of children. In civilized and primitive communities alike there is often no sharp line of demarcation between adult and juvenile games and plays, and frequently the old and the young join together for their amusements; but in the case of the adults the recreative nature of such pursuits becomes prominent. In the change of interests, in the transformation from the normal and drab to the rare and occasional, culture makes good another of the difficulties with which it burdens man. In more primitive societies recreation is very often as monotonous and strenuous as the routine work, but it is always different. Hours are spent on the completion and perfection of a small object, on practising a dance or on the artistic finish of some decorative board or figure. The activity, however, is always complementary. A type of manual or mental strain, not met in the ordinary occupations, allows man to do hard work and to tap new sources of nervous and muscular energy. Recreation thus does not serve merely to lead man away from his ordinary occupations; it contains also a constructive or creative element. The dilettante in higher cultures produces often the best work and devotes his best energies to his hobby. In primitive civilizations the vanguard of progress is often found in works of leisure and supererogation. Advances in skill, scientific discoveries, new artistic motifs, are allowed to filter in through the playful activities of recreation, and thus they receive that minimum of traditional resistance which is associated with activities not yet taken very seriously.

Plays of a different character, entirely non-productive and non-constructive, such as round games, competitive sports and secular dances, do not possess this creative function, but instead they play a part in the establishment of social cohesion. The atmosphere of relaxation, of freedom, as well as the need of larger gatherings for such communal games, leads to the formation of new bonds. Friendships and love intrigues, better knowledge of distant relatives or clansmen, competition with others and solidarity

within the competing teams—all these social qualities are developed through the public games which form such a characteristic feature of primitive tribal life as well as of civilized organization. In primitive communities there takes place often a complete sociological recrystallization during big ceremonial games and public performances. The clan system comes into prominence. The distribution into families and local groups is obliterated. New non-territorial loyalties are developed. In civilized communities the type of national pastime contributes effectively to the formation of the national character.

Art seems to be the most exclusive and at the same time the most international, even interracial, of all cultural activities. Music is unquestionably the purest of all arts, the one least alloyed with extrinsic intellectual or technical matters. Whether it be an Australian corroboree with its monotonous yet penetrating chanting or a symphony of Beethoven or the songs which accompany a dance in a pueblo or a Melanesian sailing song, art speaks alone, making use of no intellectual symbols or conventions, appealing to nothing but the direct response to combinations of sounds and to rhythm. In dancing the rhythmic effects are achieved by the movements of the body, more especially of the arms and legs, carried out in conjunction with vocal or instrumental music. Decorative art consists in the ornamentation of the body, in the various colors and shapes of clothing, in the painting and carving of objects and in representative drawing or painting. Plastic art, sculpture and architecture, wood, stone or compound structures are fashioned according to certain aesthetic criteria. Poetry, the use of language for the production of aesthetic effect, and dramatic art are in a developed form perhaps less uniformly distributed, but they are never completely absent.

All artistic manifestations operate primarily through the direct action of sense impressions. The tone of the human voice or of vibrating chords or membranes, the noises of a rhythmical nature, the words of human language, color, line, shape, bodily movement are, physiologically speaking, sensations and sense impressions. These as well as their combinations produce a specific emotional appeal which is the *matéria prima* of art and which constitutes the essence of the aesthetic appeal. At the lowest scale of artistic enjoyment are the effects of chemical sense impressions, those of taste and of scent,

which also produce a limited aesthetic appeal. The direct sensuous appeal of scents and of food and the physiological effects of narcotics show that human beings systematically banker after a modification of their bodily experiences, that there is a strong desire to be lifted out of the ordinary drab routine of everyday life into a different, transformed and subjectively orientated world. The response to sense impressions and their compounds, to rhythmic sequences, to harmony and melody in music, to the line of designs and the combination of colors, is organically founded. The artistic imperative is a primary need; it is the chief function of art to satisfy this craving of the human organism for combinations of blended sense impressions.

Art becomes associated with other cultural activities and develops a series of secondary functions. It is a powerful element in the development of crafts and of economic values. The craftsman loves his material, takes pride in his skill and feels a creative thrill for new forms which come into being under his hands. The creation of complex and perfect forms in rare and especially amenable or especially difficult material is one of the secondary roots of aesthetic satisfaction. The forms created appeal to all members of the community, give the artist a high standing and set the seal of economic value on such objects. The joy of craftsmanship, the aesthetic satisfaction in the finished product and social recognition blend with and react on each other. A new incentive to good work is given, and a standard of value is established within each art or craft. Some of the objects which have often been labeled money or currency, but which in reality are merely tokens of wealth and expressions of the value of skill and material, are illustrations of these combined aesthetic, economic and technological standards. The shell disks of Melanesia, made with special skill in a rare material, the rolled up mats of Samoa, the blankets, brass plates and carvings of British Columbia, are important to an understanding of primitive economies, aesthetics and social organization.

The deep association of art with religion is a commonplace in civilized cultures and it is present in simple ones as well. Plastic reproductions of supernatural beings - idols, totemic carvings or paintings - ceremonies such as those associated with death, initiation or sacrifice function to bring man near to those supernatural realities on which all his hopes center, which inspire him with deep apprehensions and,

in short, move and affect his whole emotional being. Accordingly, everywhere mortuary ceremonies are associated with ritualized wailing, with songs, with the transformation of the corpse, with dramatic enactments. In some religions, notably that of Egypt, the concentration of art around the mummy, the necropolis and the whole dramatized and creative representation of the passage from this to the next world have reached an extraordinary degree of complexity. Initiation ceremonies, from the crude but elaborate performances of central Australian tribes to the Eleusinian mysteries and the Masonic ritual, are dramatized artistic performances. Classical and modern drama, the Christian mystery plays and the dramatic art of the Orient have probably originated in some such early dramatized ritual.

In big tribal gatherings the union in aesthetic experiences of common dancing, singing and the display of decorative art or of artistically arranged objects of value, sometimes even accumulated food, bind together the group with strong unified emotions. Hierarchy, the principle of rank and social distinction, is very often expressed in privileges of exclusive ornamentation, of privately owned songs and dances and of the aristocratic standing of dramatic fraternities such as the *Areoi* and *Ulita* of Polynesia.

Art and knowledge are strongly akin. In naturalistic and representative art are embodied always a good deal of correct observation and an incentive to the study of the surroundings. The symbolism of art and scientific diagram are often strongly connected. The aesthetic drive integrates knowledge at low and at high levels. Proverbs, anagrams and tales, above all historical narrative, have been in primitive cultures and are in their developed forms very often a mixture of art and of science.

The meaning or significance of a decorative motif, a melody or a carved object cannot therefore be found in isolating it, in tearing it out of its context. In modern art criticism it is customary to regard a work of art as an individual message from the creative artist to his audience, the expression of an emotional or intellectual state translated through the work of art from one man to another. Such a conception is useful only if the whole cultural context and the tradition of art are taken for granted. Sociologically it is always incorrect; and the work of H. Taine and his school, who have placed all the emphasis on the relation between a work of art and its milieu, is a very important corrective to any

subjective and individualistic aesthetics. Primitive art is invariably a popular or folk creation. The artist takes over the tradition of his tribe and merely reproduces the carving, the song, the tribal mystery play. The individual who thus reproduces a traditional work always adds something to it, modifies it in the reproduction. These small individual quotas, embodied and condensed in the gradually growing tradition, integrate and become part of the body of artistic production. The individual quotas are determined not only by the personality, inspiration or creative talent of the individual contributor but also by the manifold associations of art with its context. The fact that a carved idol is the object of dogmatic and religious belief and of religious ritual defines to a large extent its shape, size and material. The fact that a mystery play is an important center of tribal life influences the way in which it may be modified and in which it has to be reproduced. Like many other artifacts or human productions the work of art becomes part of an institution, and its whole growth as well as its functions can only be understood if it is studied within its institutional context.

Culture is then essentially an instrumental reality which has come into existence to satisfy the needs of man in a manner far surpassing any direct adaptation to the environment. Culture endows man with an additional extension of his anatomical apparatus, with a protective armor of defenses and safeguards, with mobility and speed through media where his direct bodily equipment would have entirely failed him. Culture, the cumulative creation of man, extends the range of individual efficiency and of power of action; and it gives a depth of thought and breadth of vision undreamed of in any animal species. The source of all this consists in the cumulative character of individual achievements and in the power to share in common work. Culture thus transforms individuals into organized groups and gives these an almost indefinite continuity. Man is certainly not a gregarious animal in the sense that his concerted actions are due to physiological and innate endowment and carried on in patterns common to the whole species. Organization and all concerted behavior, the results of traditional continuity, assume a different form for every culture. Culture deeply modifies human innate endowment, and in doing this it not only bestows blessings but also imposes obligations and demands the surrender of a great many personal liberties to the common welfare. The individual has to submit

to order and law; he has to learn and to obey tradition; he has to twist his tongue and to adjust his larynx to a variety of sounds and to adapt his nervous system to a variety of habits. He works and produces objects which others will consume, while in turn he is always dependent upon alien toil. Finally, his capacity of accumulating experience and letting it foretell the future opens new vistas and creates gaps which are satisfied in the systems of knowledge, of art and of magical and religious beliefs. Although culture is primarily born out of the satisfaction of biological needs, its very nature makes man into something essentially different from a mere animal organism. Man satisfies none of his needs as mere animal. Man has his wants as an implement making and implement using creature, as a communing and discoursing member of a group, as the guardian of a traditional continuity, as a toiling unit within a co-operative body of men, as one who is haunted by the past or in love with it, as one whom the events to come fill with hopes and with anxieties and finally as one to whom the division of labor and the provisions for the future have given leisure and opportunities to enjoy color, form and music.

CULTURE AREA A culture area is an area set off from others by relative internal homogeneity of culture and differentiation against the outside. The concept, developed by North American ethnologists about 1890-1900 as a device for classifying museum collections, soon crept into the literature on the native cultures, and in 1917 current usage was systematized in *The American Indian* (New York 1917; rev. ed. 1922) by Wissler, who defined and mapped ten North and five South American culture areas, as follows: Eskimo (arctic), Mackenzie, eastern (north) woodland, southeast, plains, plateau, north Pacific coast, California, southwest, Nahua (Mexico), Chibcha (Colombia), Antillean, Amazon, Inca (Andean), guanaco (Patagonian). These are subdivisions of eight primary food areas, namely, caribou, salmon, seed, bison, eastern maize, intensive agriculture, manioc, guanaco. The basis is therefore economic and ultimately ecological; but in common with most American ethnologists Wissler defines the areas in terms of their culture content and uses them for cultural analysis and resynthesis. The environment, he finds, is not the cause of the culture of an area but a factor stabilizing it and tending to bind it to that area.

The most dubious part of a culture area is its border, where it intergrades with adjacent areas. Wissler therefore maps his areas only schematically and emphasizes their "centers," tracts in which the culture is most typical and intensive and which are to be construed as foci of radiation. Following Holmes he also sets up archaeological culture areas, greater in number than the ethnological ones. These have been less employed by other students, perhaps because archaeology, being often able to strike directly at the time factor in culture, is less dependent than ethnology on the indirect method of converting space distributions into time relations. Herskovits in 1924 made a preliminary delimitation of African culture areas, Cooper in 1925 occupied himself with the subculture areas of southern South America and Linton in 1928 charted the culture areas in Madagascar.

No European student has yet accepted the concept as such. Frobenius in his *Ursprung der Kultur* (Berlin 1898) defined a Congo-West African culture but made no attempt to classify

the remainder of the continent. Obermaier's placing of east European pre-Mousterian as contemporary with west European Chellean-Acheulean and Capsian of north Africa with Aurignacian-Magdalenian of Europe would in terms of American ethnological usage be cases of recognition of prehistoric culture areas; but they have not been so expressed by him and other archaeologists.

It is clear that the culture area is an empirical concept whose theoretical validation was not even attempted until after it had been in common use for at least twenty years. It appears to have originated in America because of the combination in that hemisphere of great diversity of native culture with almost unparalleled lack of historic record. The culture area corresponds to historic concepts like Occident and Orient, western Europe, India, the ancient Mediterranean world; and in biology to the faunal or floral area. It is primarily classificatory and descriptive, therefore static; but like every sound "natural" classification it implies a genetic one. The American culture areas should provide the first mechanism to an unraveling of native culture history independent of the archaeological approach. So far as they have failed in this the cause seems to lie in the fact that the areas have been too generally conceived as being equivalent to one another instead of historically subordinating and in the fact that insufficient stress has been placed on their dynamic centers.

The criticism of Boas that areal classifications of different aspects of culture, such as technology, beliefs, social forms, religion, art, music, may be non-concordant is met by the apparent fact that the culminations of these aspects tend actually to coincide in the same centers. In the historic field Athens would be an example of such coincidence of wealth, politics, art, literature and philosophy at one center. There are reasonable indications of analogous culmination centers in native America among the Maya, Pueblos, Haida-Kwakiutl, Matchez and, to a slighter degree, in the recent plains culture among Teton and Arapaho. With shift of emphasis from area to culture the idea of a cultural cycle is obviously approached.

The concept of culture area is essentially an integrating one. Where analytic tendencies are to the fore it will encounter little sympathy and much criticism. It is true that any culture area can be analyzed away as soon as interest heads in that direction. But the same is true of faunal areas, of which biologists continue to make use.

It also follows that while the culture area and age area concepts have the common objective of converting space distributions into time sequences they differ in that the age area method is most properly applicable to single culture traits or small associations of such traits, whereas the culture area (or center) is essentially intended to deal with the integration of traits into culture wholes.

There has recently been some question whether the culture area is applicable to modern civilization and to history. The answer is, first, as already stated, that culture areas are de facto although informally recognized in comparative history and sociology; second, that with reference to civilized peoples there is no need of their being thrust into the foreground, because documentation already provides the time sequence at which they aim. It is also to be remembered that civilizations like those of England and France differ from each other probably no more than cultures like those of the Cheyenne and Mandan tribes in the plains area. Czarist Russia, on the other hand, with its Greek writing and orthodoxy and general Byzantine influences was set off from central and western Europe to much the same degree as Plains from Pueblo Indian culture.

CUNARD, SIR SAMUEL (1787-1865), Canadian-English shipowner and capitalist. After a few years' experience as a merchant Cunard purchased a prize ship about 1810 and entered into partnership with his father, a timber merchant of Halifax, Nova Scotia. By 1830 the company's fleet had grown to forty sailing vessels, which dominated the Canada-West Indies trade and were beginning to offer aggressive competition to shipping interests in the United States. The Cunards in the meantime had opened a branch at Chatham, New Brunswick, to engage in lumber trade and shipbuilding. Brick and iron works were also acquired, while the younger Cunard cooperated in organizing the Halifax Banking Company. Grasping the importance of the revolution that was taking place in shipping due to the introduction of steam he subscribed £1000 to a local steamship company, which built the *Royal William*. In 1833 this auxiliary steam vessel crossed the Atlantic in seventeen days, a feat which went far toward proving the value of the marine engine. When five years later the British government became convinced of the wisdom of substituting steam for sail in its ships carrying the mails between Great Britain and North America, Cunard was commissioned to carry out the new program. A liberal subsidy was promised in the contract, but since an unusually large preliminary outlay was required, Cunard, supplying one fifth of the capital, entered into partnership with a number of leading British shipowners, who furnished the remainder. The first Cunard steamer, the *Britannia*, was launched in 1840 and shortly afterwards made a fourteen-day crossing. Three more steamers were built and in 1846, when the mail contract was renewed, the number was doubled in order to allow sailings weekly instead of semimonthly. Emphasis was placed upon safety and regularity, Cunard insisting that "steamers properly built and manned might start and arrive at their destination with the punctuality of railway trains on land." The serious competition offered during the fifties by the Collins Line of New York was met by a 50 percent freight reduction on all Cunard ships—a policy which eventually in 1858 forced the American line despite its government subsidy into liquidation. Always eager to capitalize technical improvements Cunard was among the pioneers who introduced

iron shipbuilding. In 1855 he built the *Persia*, the first iron Cunarder. In 1862 he replaced the easily disabled paddle wheels with screw propellers. Cunard's qualities of adaptability and progressiveness became the guiding tradition of the Cunard company after his death.

CUNNINGHAM, WILLIAM (1849-1919), British economic historian and churchman. He was educated at Edinburgh, his native city, and at Tübingen and Cambridge. After lecturing for several years in university extension on economics, history and literature he began teaching economic history in Cambridge University in 1878. To supply the need for an introductory book he produced *The Growth of English Industry and Commerce* (Cambridge, Eng. 1882), the pioneer general treatise. Later editions, which were practically new works, finally reached a compass of three volumes (5th ed. 1910-12). As the first of a great school of British economic historians Cunningham played a vital part in achieving results which go beyond his own work and in some cases correct it.

An essay on *Western Civilization in Its Economic Aspects* (Cambridge, Eng.) appeared in two volumes in 1898 and 1900. In it Cunningham partially discarded the arrangement of the earlier general work, which was based on the assumption that political changes dictate the main chronological divisions. Finally, in a preface to *The Progress of Capitalism in England* (Cambridge, Eng. 1916) he proposed the study of economic development systematically and altogether apart from politics as the one method of reaching the main object of economic history. This work contains a list of Cunningham's writings (p. 136-42).

A distinguished and busy churchman, Cunningham had to rely much upon highly trained assistants for the collection of materials for his more than one hundred economic monographs and articles. Among the more important are *Christian Opinion on Usury* (Edinburgh 1884), *The Use and Abuse of Money* (London 1891), *Alien Immigrants to England* (London 1897), *The Rise and Decline of the Free Trade Movement* (London 1904; 2nd ed. Cambridge, Eng. 1905)

and *The Case against Free Trade* (London 1911). These last two were polemics in favor of Joseph Chamberlain's imperial preference movement. Together with passages in the last two editions of *The Growth of English Industry and Commerce* they might well tempt one to classify Cunningham as a national economist. In this role his writings are less suggestive of List than of the German historical school, and in many ways he goes back rather to the older English traditions of Mun, Petty and to some extent Adam Smith. The evolutionary slant of his generation affected him profoundly. On the whole Cunningham's permanent written contribution to economic history is better described as honest, intelligent compilation than as brilliant synthesis.

CUOCO, VINCENZO (1770-1823), Italian historian, political writer and educator. Cuoco was born near Naples and entered the law. As a result of his participation in the revolution of 1799 he was banished from the country. He returned from exile in 1804 and until 1806 edited the *Giornale italiano*. He finally returned to Naples under Murat and Joseph Bonaparte and was appointed to the highest government offices.

Cuoco was the most profound political thinker of his day in Italy. He was powerfully influenced by the historical philosophy of Vico and was the first to make it the basis of historical writing. Cuoco's principal work, *Saggio storico sulla rivoluzione napoletana del 1799* (Milan 1801; new ed. by F. Landogna, Livorno 1927), is an admirable analysis of the reasons for the necessary failure of the movement, which he accuses of passivity, and it offers the first really incisive criticism of the abstract, antihistorical ideology of French revolutionary and pre-revolutionary thought. He looked upon these early revolutionary movements not as arising from the needs and impulses of the people but rather as promoted by a group of democrats who drew their inspiration from French political writings instead of from the popular national spirit. The history of Italy of the period, with the failure of the political reforms of the Italian princes and the Napoleonic despotism, revealed to Cuoco two inextinguishable truths; that power and freedom could be obtained only by specifically

Italian forces and not by the aid of others and that the people—"the great, the sole agent of revolution and counter-revolution" had to be won over to these new ideas if they were to be active participants. The work of the sword had to be preceded by the cultivation of a common national consciousness, by an educational revolution. Cuoco devoted all his activity as a writer, publicist and official to the propagation of these ideas. In his articles in the *Giornale italiano* (collected by Nino Cortese and Fausto Nicolini as *Scritti vari*, 2 vols., Bari 1924) and in his didactic philosophical-political novel *Platone in Italia* (2 vols., Milan 1804) he set out to realize his ideal of the regeneration of Italian public opinion, and in his famous *Rapporto al re Gioacchino Murat* (new ed. by N. Cortese in *Pensiero educativo e politico*, Venice 1928), which he presented in 1809, he developed plans for a uniform system of universal public instruction. The whole Risorgimento felt his influence through Mazzini, Manzoni and Gioberti.

CURB MARKET. See STOCK EXCHANGE.

CURRENCY is that portion of a community's purchasing power which has a conventionally or legally defined physical form and substance. Since wherever an organized state exists it defines the unit of account, currency includes all those physical embodiments of the unit of account and of its multiples or subdivisions whose form and content are regulated by law. A community employing only bank checks would possess no currency in the ordinary sense of the word, while a community in which circulating coins are not subject to legal regulation would possess circulating media but no currency. Cases in point are the trade dollar of the Orient and the Maria Theresa dollar of equatorial east Africa. Thus while all forms of currency are actually or potentially circulating media, not all forms of circulating media are currency. It is to be observed, however, that long usage sanctions the inclusion among forms

of currency not only of metallic instruments of exchange but also of paper media of general acceptability; in this wider sense currency includes banknotes which are not subject to some form of legal regulation and which would therefore fall logically outside the category of currency proper.

Since the essence of currency is that it must have a defined form and substance, the main line of cleavage is between forms of currency whose metallic content validates the face value and forms of currency whose face value is validated in indirect ways if at all. Thus the following forms of currency may be distinguished: (1) full weight coins the face value of which is kept equal to the value of the metallic content, allowance being made for mintage charges, by the right of unlimited conversion of metal into coin and coin into metal, together with the right of free import and export of both the metal and the coins (standard coins); (2) paper currency and banknotes the face value of which is secured by unlimited convertibility into metal, the amount of the metallic store being at any time equal to the amount of paper outstanding (bullion certificates); (3) paper money and banknotes fully secured by convertibility into an equivalent amount of some other currency (in an exchange standard system); (4) metallic coins the face value of which is greater than the value of the metallic content, the coins being prevented from falling to a discount either by definite rights of conversion accorded to the holder or by the readiness of the central bank to receive back surplus amounts at the face value (token coins); (5) paper money and banknotes secured by partial reserves and the right of convertibility (convertible banknotes); (6) metallic coins with a face value greater than metallic content, the value of which merely depends upon due regulation of quantity (token coins); (7) paper money and banknotes which are not convertible and the value of which depends upon the relation of quantity issued to demand (inconvertible money).

In monetary literature definite terms have been attached to some of these forms of currency. Technical phraseology, however, does not always differentiate the possible subgroups, as for example in the case of "token coins." Moreover, it sometimes creates special terms and thus distinguishes particular instances belonging to the same category which happen to be practically important at a given time. This

was true of the "limping standard" coins, the five-franc pieces of the Latin Monetary Union which retained their full legal tender quality after the closing of the mints to the free coinage of silver in 1878. Since the central banks of the countries concerned never refused to accept five-franc pieces at their face value, the "limping standard" coins were in fact tokens whose value was maintained by the de facto convertibility into other forms of currency.

The problem of adequate currency management involves two sets of considerations: economic problems relating to the maintenance of parity between the standard of value and the coin which is its physical representative, and technical questions relating to the choice of material, the denomination and physical form of the coins or notes. Even in countries where the maintenance of "external" parity has been abandoned, i.e. where the unit of account is no longer worth the number of grains of gold or silver it nominally represents, there still remains the problem of "internal" parity, i.e. exchange of the various forms of currency with one another at their face value. Modern nations are inclined to take for granted that divisionary coins of nickel, bronze or overvalued silver should always be exchanged for one another at par and should be at par with full weight coins or bank and currency notes. But the history of currency shows that perhaps the most difficult of all lessons for currency authorities to learn is the management of a divisionary token coinage. This problem was not satisfactorily solved until well into the nineteenth century. The sudden rise in the value of silver in the later stages of the World War and in the early years of the post-war decade threatened to disorganize the currency systems even of states which did not resort to inflation on a great scale, and in countries like Germany, Austria and Russia the silver coinage, even when greatly overvalued nominally, did in fact disappear altogether as a consequence of limitless inflation. This episode has left its mark on the subsequent history of currency, as in the reduction in the fineness of silver token coins in Great Britain.

The technical questions of denomination and the physical composition of the coin, also, are nowadays of real importance only in connection with the divisionary currency, since gold is ceasing to circulate and notes are convertible into foreign exchange or gold bar. Allowances must, of course, be made for the fact that even in advanced areas conditions vary greatly—

Great Britain and Germany, for example, are in this respect in advance of the United States, South Africa and Australia—and the above statement must be interpreted even less stringently in application to countries with undeveloped currency systems. The importance of the denomination relates to the effect upon retail prices of the smallest subdivision (a price less than this cannot well be charged per unit) and to the effect of alterations in the general price level upon the smallest subdivision which it is worth while to embody in the coinage. As regards the physical constitution of the subsidiary currency, the only points of importance are the desirability of substituting a circulation of small notes for coin, and the place of metallic substitutes for silver in the coinage. Experience would seem to confirm the view that a small note circulation is disproportionately expensive, involving a rapid rate of replacement and disproportionate administrative costs, and that there is little to be said for it on grounds of convenience. The use of silver or other metals is partly a question of original cost and partly a question of comparative immunity from counterfeiting. In practice, nickel and similar metals are employed for the manufacture of coins of smaller face value than silver. Thus in 1928 world coinage included over 547,000,000 silver pieces with a value of \$201,800,000, while the value of over 470,000,000 nickel and nickel-bronze pieces was only \$21,800,000 and that of nearly 700,000,000 coins of copper, bronze, aluminum-bronze and similar metals was but \$12,300,000 (Great Britain, Mint, *Fifty-ninth Annual Report of the Deputy Master and Comptroller* . . . 1928, London 1929, p. 152-53). However, this is probably a matter more of tradition than of rational expediency.

The growth of modern banking systems and the revolutionary change in the position of gold subsequent to the World War have radically altered the composition of the aggregate of purchasing power in the advanced countries. Bank deposits subject to check have grown in importance relatively to all other forms, and paper money and banknotes have increased in proportion to metallic coin. If the comparison is made with conditions a century ago, when deposit banking was unknown over the greater part of the world and was in its infancy even in Great Britain and the United States, the contrast will be found even more striking. The proportion of their total purchasing power which individuals are prepared to hold in the

form of currency or bank deposits depends upon a variety of considerations, such as the dictates of custom, the magnitude of income, the average size of payments to be made, the degree of confidence in the banking system, the freedom with which checks circulate. It is certain that with the growth of per capita wealth the proportion of purchasing power held in the form of bank deposits increases at the expense of the share held in the form of currency.

The trends described above are characteristic to a larger or smaller extent of all countries. Important differences between countries still persist, however, and these may be illustrated statistically despite the fact that detailed information on bank deposits is not always available and that the quantity of silver and other currency in existence at any moment in a particular country is subject to much doubt. Thus in the United States between 1927 and 1930 the ratio of the money in circulation to the demand deposits held by the member banks of the Federal Reserve system varied between 25 and 27 percent. A comparison of these figures with similar measures for Germany and Poland is instructive. On March 31, 1930, the balance sheets of the 92 credit banks, 21 state and provincial banks, and 17 *Girocentralen* of Germany showed deposits payable within seven days of 6,588,000,000 marks, while the total currency in circulation at the same time was 6,325,000,000 (Germany, Reichsbank, *Report of the Commissioner*, Berlin, May 17, 1930); that is, currency was nearly equal to the volume of demand deposits. The total deposits for Germany were shown at the same time as 19,790,000,000 marks; this would still give a ratio of currency to deposits of about 32 percent. On June 30, 1930, the total deposits of the Polish banking institutions were 2,908,000,000 zlotys as compared to a currency circulation of 1,539,000,000 zlotys (Poland, Bank of Poland, *Bulletin*, 1930, no. 12); the ratio of currency to deposits was thus over 50 percent. English banks do not distinguish between time and demand deposits, and no figures are available for the circulation of subsidiary currency, but in June, 1930, deposits aggregated £1,788,000,000 and notes outside the Bank of England amounted to £359,000,000, which would give a ratio of currency to deposits of about 20 percent; this is not substantially different from the American ratio if allowance is made for the roughness of the data.

Similar although not quite as pronounced

differences between countries are found in the composition of the currency, although this necessarily depends largely on the presence or absence of a small note circulation. Thus it was found that the proportion of token currency to total currency—the former being defined as “small notes, bronze and copper, nickel and aluminium, silver”—was 7.6 percent in the United States, 11.2 percent in Germany, 16.2 percent in Hungary and as high as 53.3 percent in Poland (League of Nations, *Memo-randum on Currency and Central Banks*, 1913-1925, 2 vols., Geneva 1926, vol. i, p. 23-24). It is clear that the amount of divisonary money in circulation tends to be greater, relatively to the total of all forms of money, in poor countries than in rich.

CURTIS, GEORGE WILLIAM (1824-92), American publicist and reformer. He was the son of an old and wealthy New England family. As a youth Curtis spent two years at Brook Farm, and he was well acquainted with the great literary and intellectual leaders of the day. An extended period of residence and travel in Europe, northern Africa and Asia Minor resulted in several volumes of travel papers and diaries and led him to decide upon a literary career. In an address to Wesleyan University students in 1856 on *The Duty of the American Scholar to Politics and the Times* (New York) he attacked the academian and urged the participation of scholars in public affairs. His own political activity was confined chiefly to work as a publicist. As the editor of *Harper's Weekly* he had one of the most remarkable careers in American public life. Possessed of a clear and

lucid style and a keen sense of humor he exerted a profound influence in molding American public opinion. He was a frequent and powerful orator on public questions.

Curtis early opposed partisanship and hide-bound party loyalty, demanding free discussion of all policies, and as the years passed party ties weighed less and less heavily upon him. He bolted the Republican party in the Blaine-Cleveland contest and became "the typical independent," as well as a most influential leader. He was a firm believer in the merit system of appointments, played an important role in drafting the first civil service legislation and as chairman of the first National Commission to Reform the Civil Service drafted a complete federal personnel policy. Curtis was an early protagonist of woman's suffrage and in his last years as chancellor of the University of the State of New York was active in educational work. He is an outstanding example of the middle class liberal intellectual, advocating social change by means of gradual reform under educated leadership.

W. BROOKE GRAVES

Consult: Cary, Edward, *George William Curtis* (Boston 1894); Foulke, W. D., *Fighting the Spoilsman* (New York 1919); *Orations and Addresses of George William Curtis*, ed. by C. E. Norton, 3 vols. (New York 1894).

CURTIUS, ERNST (1814-96), German historian, archaeologist and geographer. Curtius was the son of a syndic of Lübeck. He traveled extensively in Greece between 1837 and 1840 and was professor at the universities of Göttingen and Berlin. From 1844 to 1850 he was private tutor to the Prussian crown prince (later Frederick William III) and for the rest of his life was intimately associated with the royal house of Prussia. This relation enabled him to secure the establishment of the Archaeological Institute at Athens in 1873, the remarkably fine maps of Athens in 1868 and 1876, and in 1881 with the help of Moltke an equally good map of Attica. This connection also made possible the excavations of Pergamum and especially of Olympia beginning in 1875. The excavation of Olympia under his direction marks the beginning of an epoch in archaeology, for this was the first time that an ancient site had been systematically and thoroughly unearthed by a large corps of specialists in every field (among them were such men as Dörpfeld and Furtwängler) and the results superbly and promptly published.

His best known work, *Griechische Geschichte* (3 vols., Berlin 1857-67, 6th ed. 1887-89; tr. by A. W. Ward, 5 vols., rev. ed. London 1870-74), was marked by a romantic and religious idealism which completely lost sight of the Dionysian element in ancient Greek civilization. It has been called a poetical vision rather than a scientific history. Defective in source criticism, skeptical realism, politics and the evaluation of economic and social forces, it is correspondingly strong in its delineation of the great movements of culture, in its treatment of art, religion, literature and the characters of the leading men and above all in its portrayal of the intimate relation between the land and its civilization. Curtius was a disciple of the great geographer Karl Ritter, with whom he traveled at one time in Greece; and his best work, which is still a classic, is his *Peloponnesos; eine historisch-geographische Beschreibung der Halbinsel* (2 vols., Gotha 1851-52).

W. A. OLDFATHER

Berlin 1913); Kern, O., in *Allgemeine deutsche Biographie*, vol. xlvii (1903) 580-97; Fueter, E., *Geschichte der neueren Historiographie*, *Handbuch der mittelalterlichen und neuen Geschichte*, pt. i (Munich 1911) p. 497-99.

CURVE FITTING has for its purpose the graphical expression and quantitative formulation of functional or statistical relationships. Strictly speaking, it involves the use only of curves which can be described by an equation. In its looser meaning, however, the term includes also the employment of free hand curves or of curves fitted with the help of smoothing computations. This latter operation is better described as graduation or smoothing.

Curve fitting proper involves a choice of the form of an equation and of the method of fitting. In both of these stages the purpose of curve fitting is important in determining the choice. Even where only a concise description of the empirical data is sought, the investigator's interest and purpose may lead him to formulate his criterion of the faithfulness of description in some specific terms and thus to limit more narrowly the field of his choice. Where the investigator is faced with the additional task of testing some hypothesis concerning the nature of the relationship, this hypothesis will dictate the type of equation chosen.

Among the curves usually selected on such rational grounds some represent a mathematical expression of the hypothesis derived from the

study of the variable to which they are fitted. The normal curve of error or the normal probability curve describes the distribution of a variable in which the units deviate from a central tendency, determined by a constant set of factors, as a result of an interaction of a large number of small, independent, disturbing forces. This curve states the relationship between the frequency of occurrence and the size of the deviation from the central tendency, i.e. the normal. A number of variants of this curve, less definite logically, have been developed by Karl Pearson and by the Scandinavian school of Thiele and Charlier. The demand or supply curves in economic analysis describe the relationship between the price and the amount demanded or price and the supply offered. They usually embody the assumption that as the price rises demand declines and supply increases. More complex and elastic assumptions may also be made in setting up equations for demand and supply curves, as was done by H. L. Moore. The logistic and Gompertz curves in the analysis of population and industrial growth are based on the assumption that the absolute increment per unit of time is determined both by the level already attained and by the distance to the fixed upper limit of growth. The relationship is in its final form between the dependent variable and time.

In other cases the hypothesis underlying the selection of the curve may be based merely on a mechanical analogy. A typical attempt to apply to social data curves found useful in the natural sciences is the harmonic analysis of economic time series for the purpose of detecting hidden periodicity. In the simplest variant a sine curve is so fitted to the data as to reveal a typical cycle of fixed amplitude. A somewhat more elastic procedure is to fit several sine curves, or analyze the time series in reference to a more complex mechanical analogy. Generally speaking, such analysis involves undue simplification and distortion of the complex variations described by time series. The mechanical analogy is usually too rigid, and the failure to base the hypothesis upon a study of the social phenomenon itself is apt to lead to difficulties.

The use of the curves described above need not always involve the testing of a hypothesis; they could also be chosen merely because they provide a good description of the specific data studied. There are many more cases of curve fitting in which only such empirical considera-

tions are taken into account; the purpose may be merely to arrive at a compact description or to locate a "normal line," a moving central tendency. A good example is the fit of parabolic curves to price series. This type of equation is chosen not because there exist rational grounds to suppose that the relationship between price movements and time is necessarily expressed by a parabolic function, but because by increasing the order of the parabola one may get an increasingly closer fit; another reason is that the customary methods of fitting, such as that of least squares, are easily applied to parabolic equations.

Even when the choice of the equation form is based on empirical considerations, the purpose of the investigator may determine more specifically the criterion of what would constitute a good, simple, mathematically convenient description and hence indirectly the form of the equation. Thus a simple compound interest curve may be chosen because one of its parameters is the average percentage rate of change. Or it may be considered important to minimize relative rather than absolute deviations of original data from the curve fitted. If this condition cannot be readily met by using a specific method of fitting, it may be advisable to select an exponential as the type of curve to be fitted.

Once the form of the equation has been selected, we have to decide upon the method of calculating the constants of this equation in such a way that the resulting specific curve will represent faithfully the data studied. There is a variety of such methods of evaluating constants. The choice of method in each specific case will depend not only upon the more general considerations bearing on the criterion of goodness of fit but also upon empirical considerations relating to the peculiarities of the specific sample and, finally, upon such practical considerations as the laboriousness of the method and its applicability to the selected equation form.

For the determination of constants by mathematical rules it is necessary to have as many simultaneous equations as there are constants. The simplest group of methods of fitting is based on the formation of such equations from single points (selected points). Thus in fitting a curve with three constants we may choose three points out of the number available in the sample studied, form three equations and determine the constants by solving these equations.

A curve fitted by this method is bound to pass through these points, and the investigator will therefore attempt to select as such points those which represent the sample as faithfully as possible. One way of doing this is to divide the sample into as many sections as there are constants in the equation and to take the arithmetic means of these sections as selected points. The method of selected points replaces the numerous items of the sample by only a few points and may thus result in distortion. There is no assurance that the computed curve will be as close as possible to all of the items of the original data.

A more precise and more commonly used method of fitting is that of least squares. In this method the constants of the selected equation are so determined that the sum of the squares of the deviations of the original data from the curve is a minimum. As an empirical method of fitting it gives undue weight to items lying at the extreme ends of the curve; its use may therefore be misleading in some time series analyses. On the other hand, where the deviations of the original data from the curve can be assumed to follow a normal curve of error, the least squares method acquires a special theoretical significance, because minimizing the sum of the squared errors assures a normal frequency distribution of deviations as closely concentrated about its mean as is possible within the limitations of the specific sample.

Another mathematical method of fitting is that of moments. A moment is the product of the value of a given item by its distance from the central value. The moments are of the zero, first, second and higher orders, as the distance from the central value is taken to the zero, first, second and higher powers. The method of moments consists in so evaluating the constants of the curve to be fitted that each of a number of the moments of this curve (equal to the number of unknown constants) shall equal the corresponding moments of the empirical set of data. In the case of polynomials the method of moments applied to ordinates will give precisely the same result as that of least squares. Moments, however, can be used in conjunction with the more complex curves, to which the least squares method is not directly applicable. This advantage is of particular importance in the fitting of frequency curves, for which the application of the method of moments was extensively developed by Karl Pearson. In the case of skewed frequency curves another

method, that of semi-invariants, developed by Thiele, makes possible a transformation of the equation which allows much easier fitting.

Each method of fitting involves a different system of weighting the influence of items of the specific sample on the constants of the equation and assumes therefore a different criterion of the goodness of fit. The test for the goodness of fit acquires a definite theoretical significance in cases where the deviations from the curves may be conceived as items in a normal frequency distribution and where the standard deviation of the data from the curve has therefore a certain probability value. For this reason the usual goodness of fit tests as developed in sampling theory are especially applicable to curves fitted to frequency distributions, since in these cases the deviations of the empirical series from the curve can be interpreted as due to the effect of a number of independent, random causes. Even in these cases the use of such goodness of fit tests involves assumptions as to the nature of the universe which are often impossible to verify. In time series, especially in the fitting of curves to describe secular movements or to represent the scatter diagram of a correlation table, the deviations are subject to cyclical fluctuations and when taken in a certain time sequence are obviously dependent upon each other. In this type of analysis the usual tests for the goodness of fit, based upon the theory of sampling, are of no special validity; the average and the standard deviation are merely summary measures which obscure significant patterns in the time sequence of the deviations. Here the empirical judgment of the investigator, buttressed by some measures which take into account each cycle in the deviations, may be of greater value.

The fitting of curves which are not expressible by simple mathematical equations is generally called smoothing or graduation. The purpose of such graduation is not to establish functional or statistical relationships or even to arrive at compact descriptions; it is merely to eliminate seasonal, cyclical or erratic movements of the data. A more precise mathematical definition of a smooth curve is implied in the usual test of smoothness: the smaller the sum of the squares of the third differences of successive points on the curve, the greater is the smoothness.

The simplest method of smoothing is of course free hand. But the results depend too much upon individual skill and the judgment of

the investigator. The more numerous objective methods may be distinguished as falling into three groups. Polynomials may be fitted to successive sections of the data and mid-ordinates of the polynomials taken to form a smooth curve. The power of the polynomial employed may vary, and it is thus possible to distinguish methods based on second (or third) degree parabolas, and those based on fourth (or fifth) degree parabolas. Another group of methods involves replacing the original series by points of a moving average derived by various summation formulae. The simplest of these is based on the unweighted moving average, but as the requirement for smoothness becomes more rigid the number of items included in the average must be made larger and the weights assigned to successive items can no longer be kept equal. The smoothness of the weight diagram, i.e. the succession of the weights assigned in averaging to single items of the original series, is an important criterion in all smoothing methods. In the summation method, as in that of polynomials, it becomes eventually the most important determining factor in selecting the formula. Among the numerous summation schemes available we may mention Spencer's 15-term formula, Spencer's 21-term formula, Kenchington's 27-term formula and Macaulay's formulae, the latter being especially useful in application to monthly series. A third group of methods is based on the probability method of smoothing suggested by Whittaker and made practical by Henderson. This method aims at making the sum of the squares of the deviations of the data from the curve and k times the sum of the squares of third differences of the curve a minimum.

Smoothing is an operation based on the idea that the ordinates of the smooth curve should be influenced not only by the corresponding single item of the original series but also by a number of preceding and succeeding items. The period for which items are combined for the purpose of smoothing and the weights assigned to them in this combination should be decided not merely on the basis of technical considerations but also in conformity with general knowledge as to the extent to which the influence of factors measured by an item in a certain range of the series is carried over into other ranges of the same series. It is obviously unreasonable for some time series to have a method of smoothing in which an item in the year 1850 influences the ordinate of the smooth

curve in the year 1920. It is true, however, that if distant items are included with negative weights, a more closely fitting and smoother graduation may result. Similarly, the goodness of smoothing should be judged not only with respect to technical criteria but also with reference to the purpose of the operation. Thus in time series the criteria and requirements vary as we desire to smooth out only the random disturbances or also the seasonal fluctuations.

Both curve fitting and smoothing can obviously be used for purposes of interpolation; that is, for evaluating points lying between two given items of a series. There are of course other methods of interpolation which do not involve taking account of the entire series, as in the case of curve fitting, or even of such considerable sections of it as are necessary for graduation. While interpolation is usually made on the assumption that the movement of data between the given items proceeds in some regular order, which may be described by a mathematical function or approximated by a free hand procedure, this order for the limited section under discussion need not necessarily be the same as in other parts of the series. It is true, however, that in interpolations carried through according to definite mathematical formulae the implicit assumption is made that the formula used describes properly the relationship between the data in the series (dependent variable) and the scale (independent variable). In such cases one should interpolate along a curve which would provide a good fit for the entire series.

In curve fitting, graduation and interpolation, mathematics offers a variety of methods, each based upon certain assumptions concerning the nature of the functional or statistical relationship studied, the relation between the curve and the deviations from it and the criterion of the goodness of fit. An important part of the analysis is the choice of that particular type of mathematical technique which is best suited to the purpose in hand and which is most in harmony with the available knowledge of the phenomenon studied. It is essential to understand that each method is inseparable from its underlying assumptions, that there is no generally ideal procedure, that the purpose of the analysis is the real basis of choice of method and that consequently this purpose should be formulated precisely. If for some reason the mathematical technique employed is capable of yielding more exact and refined results than would be considered applicable to the particu-

lar case in the light of other knowledge of the subject, it is important to realize that the method is too powerful as compared with the data to which it is applied and that the measures obtained cannot be more precise than the data from which they have been elicited.

CURZON, GEORGE NATHANIEL, FIRST MARQUESS CURZON OF KEDLESTON (1859-1925), English statesman and colonial administrator. Curzon's mastery of Asiatic political problems, to which he had devoted himself after a brilliant career at Eton and Balliol, led to his appointment in 1899 as viceroy and governor general of India. The vigor of his benevolently autocratic administration (1899-1905), while it aroused serious controversy both in England and India, contributed materially to the rapid transformation which India was undergoing in its economic life. His concern for the welfare of the masses who subsisted by agriculture prompted him to make in their interests many important innovations, such as the introduction and enforcement of a coherent policy regarding land revenue settlement and administration, the reduction of taxes on salt and land, the establishment of agricultural banks and cooperative credit societies to protect the peasantry against money lenders, and the promotion of technical education and improved agricultural methods through the creation of the Imperial Agricultural Department and the Agricultural Institute. At the same time he gave great encouragement to the business development of India, establishing the Department of Commerce and Industry

and carrying into effect long pending currency and mining reforms as well as railway and irrigation projects. He sought to invest his regime with glamour, efficiency and a reputation for inflexible justice, but his devices for appealing to Indian sentiment ignored the rise of nationalistic feeling. Many of his policies, especially the partition of Bengal and university reorganization, provoked a volume of resentment which hastened the movement for Indian home rule. Curzon was also largely influential in securing the realignment of British Asiatic policy, with the defense of India by land as its pivot. This was manifested especially in the assertion of British hegemony in the Persian Gulf, the opening up of Tibet and the reorganization of the northwest frontier. He returned to England in 1905 and his subsequent career, which he concluded as foreign secretary from 1919 to 1924, was without distinction. Handicapped by his hauteur and love of display as well as by certain temperamental weaknesses, he was ineffective despite his unrivaled mastery of facts in enforcing his views and may be thought to have retarded rather than advanced the settlement of Europe.

CUSA, NICHOLAS OF. *See* NICHOLAS OF CUSA.

CUSHING, CALEB (1800-79), American jurist, statesman and diplomatist. After graduating from Harvard in 1817 Cushing devoted himself for some years to law and political economy, contributing essays on these and kindred subjects to the *North American Review* and other periodicals as well as translating into English (Boston 1821) Pothier's *Traité des contrats de louage maritime*. In 1826 he published a short but vigorous treatise, *A Summary of the Practical*

Principles of Political Economy (Cambridge, Mass.), in which he defended the protective tariff. From 1835 to 1843 Cushing was a member of Congress, where in 1841 he broke with the Whig party to uphold President Tyler, who later nominated him secretary of the treasury; but he was rejected by the Senate. As the first American commissioner to China Cushing negotiated the Treaty of Wang-Hiye in 1844 providing for the opening of the ports of China to United States trade. He served with great distinction as attorney general of the United States from 1853 to 1857, rendering highly significant opinions, among which was that favoring enforcement of the Fugitive Slave Law. He acted as counsel for the United States at the arbitration of the Alabama claims in 1871 and 1872, where his linguistic and legal skill was helpful in the successful settlement of the dispute. He published the proceedings of this arbitration in *The Treaty of Washington* (New York 1873). President Grant nominated him chief justice of the United States Supreme Court in 1873 but withdrew the nomination on account of partisan opposition. From 1874 to 1877 Cushing was minister to Spain, and it was during this period that his final contributions to diplomacy and the furtherance of international good will were made.

CUSHING, FRANK HAMILTON (1857-1900), American ethnologist. He was the son of a Pennsylvania country doctor and philosopher and was largely self-educated. He early became interested in Indian remains and Indians and from boyhood combined collecting, acute observation and manual training in reproducing primitive invention and technology with much fantasy enactment of the prehistoric. With the stimulation and encouragement of George Kennan, Lewis H. Morgan, L. W. Ledyard, Spencer Baird and J. W. Powell he did work for the Smithsonian Institution at the age of eighteen and became at twenty-two a member of the

Bureau of American Ethnology, with which organization he remained connected until his death. He lived at Zuñi from 1879 to 1885, excavated there and in the Gila valley from 1886 to 1888 and in Florida in 1895. Intense, intuitive, mystic, neurotic and in chronic ill health, with a streak of exhibitionism, Cushing possessed imagination and vivid insight amounting at times to genius and influenced most workers with whom he had personal contact. He had an extraordinary knowledge of Zuñi, but the fundamental monograph on the culture is by a successor, Matilda C. Stevenson, while his own writings for the most part remain disjointed fragments.

Cushing was no cabinet philosopher. He craved contact with phenomena, but he interpreted them from within himself—he "knew" their meaning with immediacy. When he presented data in organization it was according to some dramatic or symbolic system charged with significance by his personality. He derived the Zuñi numeral words elaborately and fantastically from a philosophy of hand manipulation in counting. Pottery was to him a product of attempts to represent that which interested primitive man in nature and a by-product of the use of basketry. When he found two types of burial and artifacts in Gila ruins he did not interpret them to be the remains of two successive culture periods, as they are now explained, but considered them evidence that society had been stratified into priestly nobles with esoteric rites and uninformed commoners. His observations were of the keenest, but almost impossible to disentangle from his imaginings.

CUSTODI, PIETRO (1771-1842), Italian journalist and economist. Custodi was a native of Piedmont and a lawyer by profession. During the period of unrest preceding the Napoleonic reorganization of Italy he became editor of two short lived republican newspapers, *La tribuna del popolo* and *L'amico della libertà italiana*. Napoleon caused him to be arrested but after the establishment of the Kingdom of Italy he restored him to favor, appointing him secretary general of the finance department of Milan and later state councillor. Under the empire Custodi was created baron. His fame rests upon the great *Scrittori classici italiani di economia politica* (50 vols., Milan 1803-16), in which he collected and elucidated with biographical and critical notices the writings of the chief Italian economists from the earliest times down to the beginning of the nineteenth century. To Custodi more than to any other individual is due the credit for the propagation throughout the scholarly world of the economic ideas evolved in Italy before Adam Smith. Many of the works included in his collection, such as the lectures of Beccaria, had never before been printed. Custodi also published *Cesare Beccaria* (Padua 1811), one of the early biographies of the great penologist, and *Storia di Milano* (4 vols., Milan 1824-25; later ed. 2 vols., Florence 1851), including and continuing the work by Pietro Verri. Together with Gioja and Romagnosi he founded in 1824 *Cui noli universali di economia pubblica*, which remained until its discontinuance in 1871 the leading Italian economic review.

LUIGI EINAUDI

Consult: Sangiorgio G., *Pietro Custodi, economista* (Florence 1875).

CUSTOM. The word custom is used to apply to the totality of behavior patterns which are carried by tradition and lodged in the group, as contrasted with the more random personal activities of the individual. It is not properly applicable to those aspects of communal activity which are obviously determined by biological considerations. The habit of eating fried chicken is a custom, but the biologically determined habit of eating is not.

Custom is a variable common sense concept which has served as the matrix for the development of the more refined and technical anthropological concept of culture. It is not as purely denotative and objective a term as culture and has a slightly affective quality indicated by the fact that one uses it more easily to refer to

geographically remote, to primitive or to bygone societies than to one's own. When applied to the behavior of one's own group the term is usually limited to relatively unimportant and unformalized behavior patterns which lie between individual habits and social institutions. Cigarette smoking is more readily called a custom than is the trial of criminals in court. However, in dealing with contemporary Chinese civilization, with early Babylonian culture or with the life of a primitive Australian tribe the functional equivalent of such a cultural pattern as our court trial is designated as custom. The hesitation to describe as custom any type of behavior in one's own group that is not at once collective and devoid of major importance is perhaps due to the fact that one involuntarily prefers to put the emphasis either on significant individualism, in which case the word habit is used, or on a thoroughly rationalized and formalized collective intention, in which case the term institution seems in place.

Custom is often used interchangeably with convention, tradition and mores, but the connotations are not quite the same. Convention emphasizes the lack of inner necessity in the behavior pattern and often implies some measure of agreement, express or tacit, that a certain mode of behavior be accepted as proper. The more symbolic or indirect function of a custom, the more readily is it referred to as a convention. It is a custom to write with pen and ink; it is a convention to use a certain kind of paper in formal correspondence. Tradition emphasizes the historic background of custom. No one accuses a community of being wanting in customs and conventions, but if these are not felt as possessed of considerable antiquity a community is said to have few if any traditions. The difference between custom and tradition is more subjective than objective, for there are few customs whose complete explanation in terms of history does not take one back to a remote antiquity. The term mores is best reserved for those customs which connote fairly strong feelings of the rightness or wrongness of modes of behavior. The mores of a people are its unformulated ethics as seen in action. Such terms as custom, institution, convention, tradition and mores are, however, hardly capable of a precise scientific definition. All of them are reducible to social habit or, if one prefers the anthropological to the psychological point of view, to cultural pattern. Habit and culture are terms which can be defined with some degree of precision and

should always be substituted for custom in strictly scientific discourse, habit or habit system being used when the locus of behavior is thought of as residing in the individual, cultural pattern or culture when its locus is thought of as residing in society.

From a biological standpoint all customs are in origin individual habits which have become diffused in society through the interaction of individual upon individual. These diffused or socialized habits, however, tend to maintain themselves because of the unbroken continuity of the diffusion process from generation to generation. One more often sees custom helping to form individual habit than individual habit being made over into custom. In the main, group psychology takes precedence over individual psychology. In no society, however primitive or remote in time, are the interactions of its members not controlled by a complex network of custom. Even at an early stage of the palaeolithic period human beings must have been ruled by custom to a very considerable extent, as is shown by the rather sharply delimited types of artifacts that were made and the inferences that can be drawn from some of these as to beliefs and attitudes.

The crystallization of individual habit into custom is a process that can be followed out theoretically rather more easily than illustrated in practise. A distinction can be made between customs of long tenure and customs of short tenure generally known as fashions. Fashions are set by a specific individual or group of individuals. When they have had a long enough lease of life to make it seem unimportant to recall the source or original locality of the behavior pattern, they have become customs. The habit of wearing a hat is a custom, but the habit of wearing a particular style of hat is a fashion subject to fairly rapid change. In the sphere of language custom is generally referred to as usage. Un-crystallized usages of speech are linguistic fashions, of which slang forms a particular variety. Food habits too form a well recognized set of customs, within which arise human variations that may be called fashions of food and that tend to die out after a brief period. Fashions are not to be considered as additions to custom but rather as experimental variations of the fundamental themes of custom.

In course of time isolated behavior patterns of a customary nature tend to group themselves into larger configurations which have a formal cohesion and which tend to be rationalized as

functional units whether they are such historically or not. The whole history of culture has been little more than a ceaseless effort to connect originally independent modes of behavior into larger systems and to justify the secondary culture complexes by an unconscious process of rationalization. An excellent example of such a culture complex, which derives its elements from thousands of disparate customs, is the modern musical system, which is undoubtedly felt by those who make use of it to be a well compacted functional whole with various elements that are functionally interdependent. Historically, however, it is very easy to prove that the system of musical notation, the rules of harmony, the instrumental techniques, the patterns of musical composition and the conventional uses of particular instruments for specific purposes are independently derivable from customs of very different provenience and of very different age, and that it is only by slow processes of transfer of use and progressive integration of all these socialized modes of behavior that they have come to help each other out in a complex system of unified meanings. Hundreds of parallel instances could be given from such diverse fields of social activity as language, architecture, political organization, industrial technique, religion, warfare and social etiquette.

The impermanence of custom is a truism. Relief in the rapidity of change of custom is exaggerated, however, because it is precisely the comparatively slight divergences from what is socially established that arouse attention. A comparison of American life today with the life of a mediaeval English town would in the larger perspective of cultural anthropology illustrate rather the relative permanence of culture than its tendency to change.

The disharmony which cumulatively results from the use of tools, insights or other manipulative types of behavior which had enriched the cultural stock in trade of society a little earlier results in change of custom. The introduction of the automobile, for instance, was not at first felt as necessarily disturbing custom, but in the long run all those customs appertaining to visiting and other modes of disposing of one's leisure time have come to be seriously modified by the automobile as a power contrivance. Amenities of social intercourse felt to be obstructive to the free utilization of this new source of power tend to be dismissed or abbreviated. Disharmony resulting from the rise of new values also makes

for change in custom. For example, the greater freedom of manner of the modern woman as contrasted with the far more conventionally circumscribed conduct of women of generations ago has come about because of the rise of a new attitude toward woman and her relation to man. The influences exerted by foreign peoples, e.g. the introduction of tea and coffee in occidental society and the spread of parliamentary government from country to country, are stressed by anthropologists more than by the majority of historians and sociologists as determinants of change. Most popular examples of the imposition of fashions which proceed from strategic personalities are probably fanciful and due to a desire to dramatize the operation of the more impersonal factors, which are much more important in the aggregate than the specific personal ones. With the gradual spread of a custom that is largely symbolic and characteristic of a selected portion of the population, the fundamental reason for its continuance weakens, so that it either dies out or takes on an entirely new function. This mechanism is particularly noteworthy in the life of language. Locutions which are considered smart or chic because they are the property of privileged circles are soon taken up by the masses and then die because of their banality. A much more powerful and exact knowledge of the nature of individual interaction, particularly as regards the unconscious transfer of feeling, is needed before a really satisfying theory of cultural change can be formulated.

Those customs survive the longest which either correspond to so basic a human need that they cannot well be seriously changed or else are of such a nature that they can easily be functionally reinterpreted. An example of the former type of persistence is the custom of having a mother suckle her child. There are numerous departures from this rule, yet both modern America and the more primitive tribes preserve as a custom a mode of behavior which obviously lies close to the life of man in nature. An example of the latter type of persistence, which may be called adaptive persistence, is language, which tends to remain fairly true to set form but which is constantly undergoing re-interpretation in accordance with the demands of the civilization which it serves. For example, the word robin refers in the United States to a very different bird from the English bird that was originally meant. The word could linger on with a modified meaning because it is a symbol

and therefore capable of indefinite re-interpretation.

The word survival should not be used for a custom having a clearly defined function which can be shown to be different from its original place and significance in culture. When used in the latter, looser sense the word survival threatens to lose all useful meaning. There are few customs among us today which are not survivals in this sense. There are, however, certain customs which it is difficult to rationalize on any count and which may be looked upon as analogous to rudimentary organs in biology. The useless buttons in modern clothing are often cited as an example of such survivals. The use of Roman numerals alongside of Arabic numerals may also be considered a survival. On the whole, however, it seems safest not to use the word too freely, for it is difficult to prove that any custom, no matter how apparently lacking in utility or how far removed from its original application, is entirely devoid of at least symbolic meaning.

Custom is stronger and more persistent in primitive than in modern societies. The primitive group is smaller, so that a greater degree of conformity is psychologically necessary. In the more sophisticated community, which numbers a far larger total of individuals, departure from custom on the part of a few selected individuals, who may in turn prove instrumental for a change of culture in the community at large, does not matter so much for the solidarity of the group to begin with, because the chance individual of the group finds himself reinforced by the vast majority of his fellow men and can do without the further support of the deviants. The primitive community has also no written tradition to appeal to as an impersonal arbiter in matters of custom and therefore puts more energy into the conservation of what is transmitted through activity and oral tradition. The presence of documents relieves the individual from the necessity of taking personal responsibility for the perpetuation of custom. Far too great stress is usually laid on the actually conserving, as contrasted with the symbolically conserving, power of the written word. Custom among primitive peoples is apt to derive some measure of sacredness from its association with magical and religious procedures. When a certain type of activity is linked with a ritual which is in turn apt to be associated with a legend that to the native mind explains the activity in question, a radical departure from the traditionally conserved pattern

of behavior is felt as blasphemous or perilous to the safety of the group. There is likewise a far lesser division of labor in primitive communities than in our own, which means that the forces making for experimentation in the solution of technical problems are proportionately diminished.

In the modern world custom tends to be much more conservative in the rural districts than in the city, and the reasons are similar to those given for the greater persistence of custom among primitive peoples. The greater scatter of the rural population does not generally mean the more intensive individual cultivation of the forms of custom but rather a compensatory effort to correct the threats of distance by conformity.

Within a complex community, such as is found in modern cities, custom tends to be more persistent on the whole in the less sophisticated groups. Much depends on the symbolism of a custom. There are certain types of custom, particularly such as are symbolic of status, which tend to be better conserved in the more sophisticated or wealthy groups than in the less sophisticated. The modern American custom, for instance, of having a married woman keep her maiden name is not likely soon to take root among the very wealthy, who here join hands with the unsophisticated majority, while the custom is being sparsely diffused among the intellectual middle class.

The varying degrees of conservatism in regard to custom can be illustrated in the behavior of a single individual because of the different types of social participation into which he enters. In England, for instance, the same individual may be in the vanguard of custom as a Londoner but insistent on the preservation of rural custom as a country squire. An American university man may be disdainful of customary opinion in his faculty club but be meekly observant of religious custom on Sunday at church. Loyalty or departure from custom is not a simple function of temperament or personality but part and parcel of the symbolism of multiple participation in society.

Custom is generally referred to as a constraining force. The conflict of individual will and social compulsion is familiar, but even the most forceful and self-assertive individual needs to yield to custom at most points in order that he may gain leverage, as it were, for the imposition of his personal will on society, which cannot be conquered without the implicit capture of social

consent. The freedom gained by the denial of custom is essentially a subjective freedom of escape rather than an effective freedom of conquest. Custom makes for a powerful economy in the learning of the individual; it is a symbolic affirmation of the solidarity of the group. A by-product of these fundamental functions of custom is the more sentimental value which results from an ability to link the present and the past and thus to establish a larger ego in time, which supplements with its authority the larger ego represented by the community as it functions in the present.

The formulation of customs in the sphere of the rights and duties of individuals in their manifold relations leads to law. It is not useful to use the term law, as is often vaguely done in dealing with primitive societies, unless the enforcement of customary activity be made explicit, being vested in particular individuals or bodies of individuals. There are no societies that are wholly free from the binding force of implicit law, but as there are also many primitive societies which recognize some type of legal procedure it seems much better to speak of law only in the latter case. There are, for instance, few American Indian tribes in which customary obligations are recognized as a system of law that is capable of enforcement by the community. Psychologically law prevails, but not institutionally. This is in rather sharp contrast to the legal procedure which has been developed by the majority of African tribes. Here there is not merely the law of custom in an implicit sense but the perfectly explicit recognition of rules of conduct and of punishment for their infringement, with an elaborate method of discovering guilt and with the power of inflicting punishment vested in the king. The example of African law indicates that the essential difference between custom and law does not lie in the difference between oral tradition and the written formulation of custom. Law can emerge from custom long before the development of writing and has demonstrably done so in numerous cases. When custom has the psychological compulsion of law but is not controlled by society through the imposition of explicit penalties it may be called ethics or, more primitively, mores. It is difficult to distinguish law and ethics in the more simple forms of society. Both emerge from custom but in a somewhat divergent manner. Mundane or human sovereignty becomes progressively distinguished from socially diffused or supernatural or impersonal sover-

cignty. Custom controlled by the former is law; custom controlled by the latter is ethics.

The agencies instrumental in the formation of custom are for the most part quite impersonal in character and implicit in the mere fact of human interrelationships. There are also more self-conscious agencies for the perpetuation of custom. Among these the most important are law and religion, the latter particularly in the form of an organized church and priesthood. There are also organizations which are sentimentally interested in the conservation of customs which threaten to go out of use. In the modern world one often sees a rather weak nationalistic cause bolstered up by the somewhat artificial fostering of archaic custom. Much of the ritualism of the modern Scottish clans is secondarily rather than linally conservative.

If complicated forms of conscious manipulation of ideas and techniques which rule the modern world are excluded from the range of the term custom, the force of custom may be said to be gradually lessening. The factors which favor this weakening of custom are: the growing division of labor with its tendency to make society less and less homogeneous; the growing spirit of rationalism, in the light of which much of the justification of custom fades away; the growing tendency to break away from local tradition; and, finally, the greater store set by individuality. The ideal which is latent in the modern mind would seem to be to break up custom into the two poles of individually determined habit on the one hand and of large scale institutional planning for the major enterprises of mankind on the other.

CUSTOMARY LAW. In its origin customary law appears to be only a differentiated form of general custom. The basis of both law and custom is precedent, which, according to Holland, is illustrated by "the mode in which a path is formed across a common." One man crosses either by accident or design; others are likely to follow in the same track until a path is worn. Pollock cites the child's appeal to precedent in order to avoid some present parental prohibition, and the force of habit prevails in the whole early history of the race. But while the mechanical repetition of acts explains the origin of many usages which come to be recognized as law, it does not indicate the point at which the differentiation between law and custom occurs.

The problem of the nature of customary law has been prominent in juristic theory, and the conclusions reached by jurists have depended upon their views of the nature of law in general. The two dominating modern theories have been those of the analytical school of Austin and the historical school of Savigny. The former, regarding law as the command of the political state prescribing a certain line of conduct in all cases of a similar character, enforceable by specific sanctions in the event of disobedience, has tended to slight customary law and scarcely to admit its existence. On the other hand, the historical school has tended to exalt customary law as a spontaneous expression of the genius of a people, arising from its juristic consciousness and determining subjectively when rules shall be regarded as legal. Later jurists have variously exhibited the influence of both views.

Thus Maine issues a warning against the application of the Austinian view as a test of customary law. He implies that custom begins to be law when it is brought into dispute and some means is provided for declaring or recognizing its obligatory character. According to Munroe Smith customary law arises at "the point at which the infliction of penalties affecting the property or the person begins to be assured." In other words, custom does not become law until it acquires a clear and definite sanction. However much this may be true of a mature legal system, the better opinion is that it is not true of customary law. In early law sanctions are often imperfect and informal. Thus hardly anything more can be said than that custom becomes law when it is recognized in some way as governing a class of relations segregated as juridical, i.e. the family, debt, injury.

Although it is difficult to say exactly when

custom becomes law, it is possible to single out some of the factors in the transition. A custom comes to be accompanied by some ceremonial, borrowed no doubt from religious ritual but really differentiating the transaction as creating relations of an obligatory or formal character. The Hindu *Brahma vivaha* or the Roman *confarreatio* and mancipatory sale may be cited as instances. The religious nature of the ceremony gives the relations it creates a particular solemnity. Primitive formalism, indeed, surrounds the transactions of everyday life. Another step toward juridical consciousness may be illustrated by the regulations and safeguards that begin to surround the right of self-help—a prominent feature of primitive relations. The imperfectly obligatory character of early law is emphasized by the preservation of fictions of voluntarism in procedure, which thus helps to stress its customary basis.

It is a particular characteristic of customary law that the availability of a judge is more important than the availability of settled rules of law. The right of judgment thus has to be vested in some person or class of persons, e.g. in the priestly or aristocratic class; but later resort is had to more popular "law finders." Customary law, then, represents that intermediary stage in juridical evolution when law has ceased to be conceived simply as the will of the gods, *fas* (compare also the Hindu *dharma*), and its transgression as *nefas*, entailing the divine displeasure, and an additional sanction has been found in the fact that judgments are supposed to derive their force from the existence of popular custom.

The law finders have been very important in the early development of many systems. The early Roman law was known chiefly to the College of Pontiffs, to which even the judges resorted and which private parties consulted regarding court days and the proper steps to be taken in the formation of contracts and the conduct of litigation. The answers to these inquiries became precedents and were the forerunners of the *responsa prudentium* of later times. Among the ancient Hindus law was regarded as in the special custody of a learned priestly class. Among the early Teutons, however, the law speakers were not of a sacerdotal character. They were the elders, and their judgments had to be approved by the freemen, who gave, as it is said, the *Volkwoort* (full word). In Iceland, typical of Scandinavia as a whole, a law speaker also was charged with the declaration of the law and the

recital of the Thing rules of procedure every summer.

But even where popular approval is apparently necessary, it is of course the functionaries to whom the right of interpretation of customary law has been entrusted rather than the whole body of the people who shape it. For they not only declare what that law is but their utterances afford a precedent for similar declarations thereafter. Just as general custom is developed by following precedent, so customary law grows and expands in the form of such decisions. Customary law thus becomes a system of "case law," differing, however, from the modern type in the character of its authors. As Vinogradoff has very well put it, "we may say that customary law appears as the judge-made law of periods when the judges are still intimately connected with the people they represent, and feel bound to declare popular legal lore rather than to supply links in a system of learning."

The historical school conceived of customary law as the expression of the genius of a whole people. But in truth customary law is at first distinctly local and the law of only a very small locality at that. This is, indeed, one of the conditions of its growth. But as the customs of contiguous or affiliated tribes are likely to be similar, at least in their broader aspects, the political union of tribes through conquest usually results in the development of a customary law common to the people of a whole area. But naturally the process would not always be complete, for some localities cling more tenaciously to their customs than others.

Above all, customary law, being a primitive form of positive law, flourishes as unwritten law. "Except this," declares Sir Henry Maine, "there is no such thing as unwritten law." As soon as writing begins to be generally employed, law correspondingly ceases to be customary. But the art of writing is often known for very long periods before it is employed in expressing customary law in whole or in part. Writing was, for instance, known in Greece long before the code of Solon. It is felt rather that the reduction of the law to writing tends to undermine its popular or customary basis. When the step is taken it is usually in response to conditions of social conflict that have brought confusion into the law. Even while it remains unwritten, however, customary law may acquire in part a form of its own, as in *gnomes* or *maxims*. "The expression, in clear and memorable sayings," observes Munroe Smith, "of the rules implied in

the decisions . . . to primitive men seemed real law-making. . . .” Moreover, writing may be used at some stage of the judicial procedure without destroying the character of the law as customary; and indeed the law may continue to be regarded as such even after decisions are reported in writing, provided they are still supposed simply to express popular legal lore. For in a juristic sense law has been regarded as unwritten although it is not such in a literal sense. The Romans apparently interpreted the phrases *jus scriptum* and *jus non scriptum* literally, but modern civilians have applied the former only to commands issuing from the supreme power in the state. As a matter of terminology the application of the term customary law has often been purely arbitrary. Roman law has not been spoken of as customary after the Twelve Tables. Yet, after all, the juriconsults were only law finders. The explanation would seem to lie in the maintenance of the fiction that their declarations of the law were only “interpretation” of the tables. Moreover, Roman law had become a learned system.

In a similarly artificial way the term customary law was applied at the close of the Middle Ages to the local bodies of law which had been crystallized after the dissolution of the Roman Empire, although they had then already entered upon a formal juristic stage. Customary law then meant hardly more than local law. But in the early mediaeval period true bodies of customary law had flourished. The times were well suited to such a development. It has already been pointed out that customary law is primarily local law, and the multiplication of local jurisdictions under the feudal system is well known. Since no strong central government existed, local popular justice alone could survive. Even the imperial Roman law was converted into subsidiary local custom. Family law and land law have always tended to be the special provinces of customary law, and this was especially true in the Middle Ages. Indeed, mediaeval law was developed in ways that recall all the characteristic factors of the evolution of customary law.

The importance of the law finders is an illustration. In the church these were naturally wholly sacerdotal. But in the temporal courts, which applied customs predominantly Germanic, the law finders were naturally lay and popular. In the Frankish Empire the *scabini* and in Scandinavia the later *lagmen* became official law finders. The customary law of mediaeval Germany grew from the findings of the

Schöffen, or lay judges; doubtful cases were resolved by the adoption of a *doom*, i.e. a declaration as to the nature of the rule of customary law, after an official inquiry by the local law finders. In manorial communities the law for the current year used to be settled annually on definite days upon the basis of an official *inquisitio*. The manorial official (steward or bailiff) asked in the *halimot* (assembly) for guidance upon the law in a given case, and he received answer upon oath. The topics of customary law were more or less completely exhausted by this exchange. Declarations of rural custom, the *weistümer* or *öffnungen*, were made annually at certain periods by the elders in the village assembly.

The variety of the mediaeval bodies of local customary law, variously compounded of indigenous and Romanic elements, is bewildering. In the various Spanish kingdoms prevailed the so-called local *fueros*; in northern France the *coutumes*. In the Teutonic regions of the north the early customary law applied in the ordinary German courts was known as *Landrecht*; but there were other forms, such as *Lehnrecht* (law of the fief), *Bauernrecht* (peasant law), *Stadtrecht* (town law), *Hofrecht* (manorial law) and *Zunftrecht* (guild law), all characteristic of the special types fostered by the feudal system. To illustrate beyond the orbit of western European law, the term *zakon*, common to several Slavic languages, once meant customary law and designated a system prevailing among the various nations using the Slavic tongues. The reception of the Roman law ultimately undermined, without completely destroying, these bodies of customary law. Roman law, embodied in the *Corpus juris*, was called *jus scriptum* in contradistinction to the customary law although it represented chiefly jurisprudential sources. But toward the close of the Middle Ages the customs, already modified by intrusions of Roman law, began to be reduced to writing and to become the domain of formal jurisprudence, thus indicating that they were losing their character as true customary law even though they remained local in application.

In Spain the earliest attempts to set forth any of the general law prevailing in any of the kingdoms were made with respect to the *fueros* of León and the *usatici* of Catalonia in 1068. But at the end of the tenth century the Conde de Castilla inaugurated the preparation of what ultimately became known as *El fuero viejo*. At the Cortes of Nájera in 1137 the *fuero* of this name, known also as *El fuero de los fijosdalgo*, or

Book of Decisions and Arbitrations, was ratified and the Cortes of the same place in 1176 made additions to the *El fuero viejo*, in connection with which Alfonso VIII in 1212, confirming charters granted by two of his predecessors, charged the hidalgos and nobles "to search their records and write down the good laws, customs, and decisions." And while the king withheld his approval even after this was done, it is said that judgments were rendered according to the *fuero* written in this book and according to these decisions until 1254-55, when Alfonso X issued the famous *Fuero real* for Castile. The *Compilación de Canellas* (named after the bishop who had prepared it), or the *De fuesca*, of 1247 reflects the customary law of Aragon. A general *fuero* for Navarre is ascribed to about 1237, although it may have been later, and was revised in the following century; while general *fueros* for Valencia were promulgated in 1239 and revised about a generation thereafter. In France the need of reducing the *coutumes* to writing finds earliest expression in the thirteenth century, but through private initiative, for public authority showed no interest. The *Grand coutumier de Normandie*, which codified the customary law of that region, was probably composed about the middle of the century. Soon there appeared Pierre de Fontaines' *Conseil à un ami*, which compiled the customs of Vermandois, relating to procedure, but combined them with extensive extracts from the *Corpus juris*; the *Liivre de justice et de plet*, less than half of which treated the *coutume* of Orléans, the rest being translations of Roman texts; and the *Établissements de Saint Louis*, treating the same *coutume* and that of Touraine-Anjou but with the usual translations from Justinian. About 1280 Beaumanoir, a scholar as well as a judge, wrote his *Lièvres des coutumes et des usages de viavouvoizins*, which was not only a compilation of the customs but a treatise on customary law. Beginning in the same century there were compilations of the *coutumes* for Anjou, Berry, Poitou and Maine. About 1282 appeared the *Anciennes constitutions du châtelet* of the court of the provost of Paris containing the current rules of customary law and procedure; in the following century there appeared a compilation of customs for Brittany. Toward the end of the fourteenth century Jacques d'Ableiges compiled the *Grand coutumier de France*, treating largely of procedure and including rules from the *Coutume de Paris*; and Jehan Boutillier published his famous *Somme rural*, which includes the customs of northern

France and exhibits the evolution which the customary law was undergoing. Thus by the opening of the fifteenth century the law in at least the part of France which had come to be known as *Le pays de droit coutumier* had been reduced to writing in fragmentary treatises generally accepted as authoritative. But there was a natural demand for compilations which would be official and more complete, and in 1453 Charles VII promulgated the *Ordonnance de Montils-les-Tours*, article 125 of which directed that the *coutumes* be officially compiled. There was a long delay in carrying out the project, and the first *coutume*, that of Ponthieu, was not actually written down until 1494. The *coutume* of Orléans was compiled in 1509; that of Paris which became the model for the colonies, in 1510 and that of Brittany in 1539. It is estimated that the 360 groups of an earlier period were now divided into 60 general and 300 special *coutumes*. After their redaction a long line of learned French jurists busied themselves therewith. In the Germanic countries *Hofrecht* and *Stadtrecht* began to be written down quite early. A body of the former compiled at Reichenau dates from about 1150, although forged in the name of Charlemagne under the title of *Constitutio de expeditione romana*. A notable compilation of *Stadtrecht* for Muhlhausen in Thuringia was prepared about 1250 and toward the end of the same century the local laws of Goslar were compiled by order of the municipal council. These are but instances of numerous like productions appearing in various parts of Germany. Meanwhile, about 1230 both *Landrecht* and *Lehnrecht* were collected and published in Latin by the *Schöffe Eike von Repkow* as the *Sachsenspiegel*. It soon became not only a source but a authority throughout the country and as such naturally superseded the customary law which it embodied. It was imitated in the *Deutschenspiegel* (c. 1250) and the *Schwabenspiegel* a few years later, but these already show the influence of Roman law, which was in the process of reception throughout Germany.

The common law of England in its classical period well illustrates the conception of customary law. The English common law grew originally from the collections of tribal customary law made successively by Alfred, Edgar and Edward the Confessor. When the royal law courts obtained jurisdiction over the whole kingdom as a result of political centralization they welded these special local customs into one general custom of the realm, although some of the former

survived—as in Kent, which even in Blackstone's day retained its custom of gavelkind in derogation of primogeniture. The local customs were originally popularly declared. This function was discharged in Saxon England by the wise men (*witan*) in the county courts; indeed, Parliament in the Middle Ages came to be considered the chief organ for the declaration of law. The name long borne by the developing system of English law was *Leges et consuetudines angliae* or "the custom of the realm." Indeed, Munroe Smith has asked: "If the English Common Law is not the general English custom, what is it?" But the question implies the answer. The very fact that it had become a general law shows that it had ceased to be customary. After the Year Books it was certainly developed by a professional class of lawyers and judges whose learning can hardly be called popular. It is true that the fiction was long maintained that the judges merely "found" a previously existing law and declared it; indeed, this idea is found in Blackstone, but it had long ceased to be true. The reported precedents were themselves considered as embodying the law and were authoritative and binding. This "case law" was thus quite unlike the so-called jurisprudence of the civilians, which was regarded merely as the opinions of those learned in the law. Case law was "scientific law" which was authoritative from the moment of its creation. Nevertheless, since the classical common law was almost exclusively a system of precedents it was most reminiscent of customary law. But in a highly developed legal system not all problems can be solved precedent by precedent, and legislation has come to play almost as great a part in common law as in civil law countries. While the common law as a whole has never been codified, vast portions of it have passed into statutory form. But in an earlier stage it showed itself strikingly capable of absorbing a whole body of customary law without the aid of legislation, e.g. the law merchant, a system of mercantile usage.

In all legal systems, however, advanced local customary law continues to play some supplementary part in the adjustment of local interests. The *Corpus juris civilis* was supposed to embody the entire Roman law, yet in the *Institutes* it recognized "the unwritten law which usage has approved." Customary law was recognized in turn, in derogation of the received Roman law, by the mediaeval jurists, canonists as well as civilians. The modern continental codes often recognize the old legal customs in certain re-

spects; it is sometimes provided that where no statute is directly applicable the local custom shall be applied. Old types of land tenures or some of their incidents have survived in this way. Under the common law also special customs have sometimes been admitted although contrary to the general rule.

But when a custom is juristically recognized in this way it becomes part of the general law. If it is not a creation it is at least an adaptation of mature jurisprudence. This is shown by the fact that before it will be admitted it must pass certain juristic tests. Upon these, however, there has been very little agreement among jurists. The glossators held that a custom must meet the requirements of antiquity and reasonableness. Bartolus stipulated *longum tempus, tacitus consensus populi, frequentia actuum*. Under the canon law custom was recognized when it became *legitima praescriptio*, i.e. subject to the time requisites of prescription. Blackstone gives a long list of conditions: a custom must be immemorial, reasonable, continuous, peaceable, certain or clear, compulsory, consistent with the rest of recognized custom and not against an act of Parliament, and if against the common law it must be strictly construed. Generally, the more highly developed a legal system, the less likely it is to admit inconsistent custom. The word immemorial must not be too literally understood. In the common law the period of legal memory is supposed to run from the accession of Richard I (1189), but in practice a custom that goes as far as "living memory" is presumed to date from Richard I.

Besides the occasional recognition of old customary law in individually litigated cases modern times have afforded the phenomenon of its wholesale or extensive reception in some places. Hindu law, which is largely customary, is now being extensively applied in the courts of British India. Custom still plays a part in adjusting law to new situations even in highly codified systems and thus is a continuing source of contemporary law. This is particularly true in constitutional law, which even where a written constitution exists tends to become largely customary. International law has been called customary. One of the modes of infiltration of customary into positive law is through "interpretation" of the written law. Appeals are made to the "unwritten law" before juries in accordance with persistent prevailing conceptions of "right" and "wrong." In this way unpopular criminal statutes particularly have often been

practically nullified. When one considers the immense mass of modern legislation, often incoherent or anachronistic, it is interesting to recall certain intimations of the ancient Roman jurists that even law of legislative origin might be superseded by contrary custom.

CUSTOMS ASSIMILATION. See COLONIAL ECONOMIC POLICY.

CUSTOMS DUTIES in the modern sense of the word are public taxes on goods crossing the border of a territory. They are taxes and not fees since there is no return service rendered by the corporate body which levies them. They may of course be accompanied by supplementary charges which partake of the nature of fees, such as charges for the use of special equipment in customs offices, for the storage and protection of

goods and to cover the cost of trade statistics. Customs duties may be distinguished from other taxes fundamentally in that their predominant purpose is not financial but economic—not to increase state revenue but to promote home industries as against foreign competition.

Duties first developed into taxes levied at the boundary in the eighteenth and nineteenth centuries. Before that time duties levied on trade took the form of tolls for the use of streets, rivers, bridges and harbors or for protection and safe conduct of persons or goods. These were levied not at the borders but at important trade centers and market towns within the country, with no discrimination between import, export and transit goods and without regard to whether or not a similar fee had already been paid in another part of the country. Gradually there appeared a definite distinction between fees collected at bridges and city gates, which were called tolls (*octrois*, *Mauten*, *Akzisen*), and fees collected at the border on entrance to, or exit from, a national territory, which were called customs duties (*droits de douane*, *Zölle*).

This differentiation was called forth by mercantilist doctrines under which each country strove to become a self-sufficient economic territory and to regulate foreign trade in the manner most favorable to its own production and exports. Tariff for revenue only was subordinated to tariff for protection, and emphasis was laid on import duties. There were to be low rates or exemptions for goods which the country needed for manufacture and high rates on finished products which were competing with home industries. In the last quarter of the nineteenth century the increasingly sharp competition of overseas nations forced continental countries to extend protection to agriculture by import duties on such products as grains and meat. Export duties, which seldom appear and have been entirely abolished in most countries, may also serve an economic purpose if the country has a natural supply of raw materials which it wishes to reserve to domestic manufacture. Transit duties have been gradually discarded everywhere since the middle of the nineteenth century, for with the present great development of commercial relations it is no longer possible to regulate the transit trade for the benefit of home industries and exports; on the contrary, every country must strive to direct the largest possible amount of world traffic over its own railroads and steamship lines. On April 20, 1921, an international convention was concluded

ed in Barcelona regarding free transit of goods.

The mercantilist trade policy, which led to the establishment of a system of frontier duties, required at the same time the abolition of all remaining internal tolls, which separated the different provinces or territories of the same state from one another. Tremendous obstacles, due principally to old political arrangements, had to be overcome in order to accomplish this. In some places these internal tariffs continued until very late times, as in Turkey, Brazil and especially in China. In the last named country the so-called *likin* taxes, the widespread application of which dates from the necessity of covering the cost of the suppression of internal uprisings during the sixties of the last century, were retained by the Chinese government in contrast to the customs duties which were pledged to foreign powers. They were legally abolished in 1930, effective January 1, 1931.

Although the fiscal motive of revenue from import duties has been pushed far into the background by the economic end of protection for home industries, it has not entirely disappeared. Duties purely for revenue still exist in all countries. They are usually import duties on goods which are not produced in the country, whose value is not increased by further manufacture after importation but which are intended for personal consumption, such as coffee, tea, spices and tobacco. They are the simplest and most effective taxes on consumers of foreign goods, and their only defect from the point of view of social political principles is that they must be levied on objects of mass consumption and cannot be graded according to the purchasing power of the consumer. Furthermore, the higher the duty and the greater the value of the article in relation to its volume, the greater the temptation for smuggling. In consequence it has often been found advisable to reduce the rate of a fiscal duty in order to increase its productiveness. Export duties may also bear the character of fiscal duties, but only when they are levied by countries so predominant in the supplying of some tropical agricultural product or some mineral product that they can pass on the burden of the tax to the foreign consumer without impairing the market for the product taxed. The possibility of doing this is decreased by the diffusion of animals and plants and by the invention of artificial substitutes.

Most duties, however, have become protective duties levied on the importation of goods whose domestic manufacture must be protected against

foreign competition and on the exportation of raw materials and by-products which should be used in home industries. There is no very clear line of demarcation between fiscal and protective duties, for many a revenue duty affects some competing industry within the country. The revenue tariff on rice influences domestic grain cultivation and that on tropical fruits affects home cultivation of fruit. With the spread and increase of protective tariffs the financial profit from them has become of some importance for the national budget. Some nations derive more than half their revenue from customs. It is not possible to compare the percentages for the several countries, since the bases for the statistics are too diverse. Foreign trade is relatively much more important in smaller countries than in larger. In federations tariff revenue usually goes to the treasury of the union and consequently assumes a much greater importance than in countries where there is no division of revenue between federation and individual states.

The customs duties of a country are combined into a customs tariff according to some systematic arrangement, usually by groupings of goods. This tariff forms the basis for the negotiation of commercial treaties with other countries and therefore frequently contains high rates which can be lowered in the course of the negotiations to meet concessions from the other side. With an eye to these commercial treaties the tariff is rarely a single tariff, with one rate for each article regardless of the country from which it comes, but is usually a double tariff, composed of two columns, one with lower rates for most-favored-nations, the other with higher rates for all other nations. The double tariff may further be either a general and conventional tariff or a maximal and minimal tariff. In the first case the lower or conventional tariff consists of the reductions conceded to individual nations through commercial treaties; in the latter case both minimal and maximal tariffs are set by law and cannot be lowered by treaty concessions. The latter system protects home producers from unexpected and inconvenient changes through subsequent treaties but renders reciprocal tariff reductions more difficult, because the rates of the minimal tariff are secured through the mere granting of most-favored-nation treatment. This system, however, has spread considerably during the past decade, especially through French action. A tariff may consist of more than two columns, particularly

when it includes preferential rates between a mother country and her colonies. There is then a general rate for non-favored-nations, an intermediate rate for most-favored-nations and a preferential rate for the mother country or the colonies. French tariffs have sometimes contained even more rates for the same goods, because certain countries received rates lying between the maximal and the minimal.

There are also differential tariffs, which may consist either of a reduction in conventional or minimal tariffs or of an increase in general or maximal tariffs. Through the spread of most-favored-nation clauses since the middle of the nineteenth century the occurrence and the area of applicability of differential tariffs have been greatly diminished. Formerly there were levied frequent "flag surtaxes" (*surtaxes de pavillon*), percentual surcharges on goods brought in on ships sailing under foreign flags. These played a large part in the older trade policies of England and France and aimed at increasing the share of the country's own merchant marine in overseas trade. Their widespread use, however, affected most seriously those countries which were most interested in shipping. Surcharges for indirect imports (*surtaxes d'entrepôt*) were formerly laid on goods that on their way from producer to consumer passed through a third country, which then profited as intermediary. These still occur in several national tariffs. In Austria there was an isolated case of special rates for sea traffic as against land traffic, but the arrangement was successfully attacked as being incompatible with most-favored-nation treatment.

Favorable tariffs to effect a closer economic union between politically independent states have been tried repeatedly, but they are not compatible with preexisting most-favored-nation treaties. Preferential rates between mother country and colonies have become very important, particularly in the British Empire. Lately frequent antidumping duties have appeared, to combat the bad effects on home industries of foreign exports which could sell for less because of state export premiums, cartels and trusts, progressive depreciation of currency or poorer labor legislation. Customs laws also provide for tariff wars with countries which treat imports unfairly. The law empowers the government in such cases to levy retaliatory duties, which means raising all general or maximal rates by a certain percentage.

The basis of appraisal may be either *ad valorem*, according to the value of the article, or

specific, according to some measure of quantity, usually weight. The great advantage of the *ad valorem* method is the automatic adjustment of the duty to the stage of manufacture as well as to variations in price due to differences in quality or market fluctuations. Its disadvantage is that the value is not definite and must be determined by the customs administration by difficult and always uncertain methods. Specific duties, on the other hand, are more convenient in that customs officials may easily determine them by weighing, measuring or counting. But under them the tax burden diminishes with the stage of manufacture, which increases value in relation to volume, and the proportion of the tariff burden to the value of the goods varies inversely with changes in price. The first objection is weakened by the graduation of specific duties as much as possible according to the various quality grades of the goods, although this again introduces the necessity for extremely complex and highly technical machinery for appraisal as well as an enormous expansion of the tariff list, which already in industrial nations contains hundreds of items. The second difficulty can be overcome only by the adoption of a new tariff, which always involves wearisome preparation and violent conflicts between opposing interests.

With the predominance of the protective over the fiscal viewpoint each country strives to make its political territory correspond to its customs area and to consider its political frontiers as customs boundaries, the crossing of which determines the collection of duties. This ideal is not always attainable, however, since the boundaries of a country are fixed by political treaties which emphasize such factors as military security and nationality of population and often seriously disturb economic relations of long standing. The unity of the customs area is further limited by the fact that a strip of territory ten to fifteen kilometers in width along the border is granted special privileges in order to help the border inhabitants to earn a livelihood and to develop agriculture on property which is cut in two by the boundary line. This border zone must be carefully watched for smuggling. It is often necessary to conclude a special treaty with the neighboring state concerning border trade, which is expressly excluded from most-favored-nation treatment. It sometimes happens that parts of its own political territory are excluded from a country's customs area or that sections of another state are included in it. Exclusion may be due to a desire to encourage

international traffic in the excluded zone by its complete freedom from customs, as in the so-called free ports and free zones. Or certain places may be so separated from their own country as enclaves or by geographical barriers that it is to their own economic interest to be attached to the customs area of another nation. Examples of this type appear in certain communities in Germany, Austria and Switzerland. Even entire small states may be incorporated in a foreign customs area. Thus the principality of Monaco is attached to France and Lichtenstein to Switzerland (having been joined to Austria before the war). Luxemburg was attached to Germany before the war and is now in customs union with Belgium. Incorporation into a customs territory differs from entry into a customs union in that the smaller state takes over the customs regulations and commercial treaties of the larger state without being able to influence their content, while the customs union rests on a basis of parity, so that previous acceptance must be sought before any measures of commercial policy are taken.

Customs duties are no longer the only means of protecting home industry against the unfavorable influences of international economic relations. Numerous other protective measures aside from legislation have been developed and applied by the administration or by organization among the people themselves. In countries where the railroads are state owned, railroad rates are often used for this purpose. To prevent this commercial treaties include the principle of internal parity, which permits no discrimination in transportation rates between domestic and foreign persons or goods. This parity has shown itself to be only a formality, however, for it does not hinder variations in import and export rates injurious to foreign traffic, which uses the same stretch of road as domestic traffic but usually in the opposite direction. In the direction of import traffic the freight rates are kept low on raw materials and semimanufactured products, which are not produced in sufficient quantities in the country but which are needed for production, and high on finished articles, which need protection against foreign competition. In the export direction rates are low on goods for which it is desired to encourage a foreign demand and high on raw materials which supply foreign competitors. By means of such differential railroad rates the effect of the home tariff may be strengthened and that of the foreign tariff weakened. The use of this protective

measure is much easier than the laying of customs duties; for the latter, as government taxes, arise from extensive and difficult acts of legislation, while freight rates, which are a compensation for transport, can be altered by the railroad administration at any time.

In many European states veterinary police regulations and quarantines are abused for commercial purposes. The danger of the introduction of contagious animal diseases made import prohibitions necessary, and certain clauses were included in commercial treaties to provide for these by expressly exempting those goods which must be restricted on sanitary or safety grounds. By a widespread application of this measure cattle raising has been protected not only against the introduction of animal epidemics but also against foreign competition. Patent, trademark and copyright laws, passed for protection of industrial property, and laws against unfair methods of competition are frequently administered so as to hinder seriously the importation of foreign manufactures. In the case of public supplies the authorities are often obliged to give preference to home goods even when they cost more, and details of the terms of delivery may be formulated to the advantage of the home producer.

Finally, the people themselves can adopt a policy of self-help without government aid or even in the face of the government's express disapproval. Such were the boycotts on foreign goods not infrequent in the last decade and primarily political in their origin. More subtly economic and less openly aggressive are the attempts to create a preference for home goods by a heightening of the national consciousness through the creation of a national trademark or through general propaganda to "buy home goods."

The fixing of the tariff is a legislative right. It has, however, become more and more difficult in the course of time, partly because with the increasing specialization of customs duties more expert technical and economic knowledge is required, and partly because every item means interference with the conditions of a particular branch of industry and the relation between production and consumption. Here appears especially acutely a problem apparent also in other fields of economic policy—the problem of how to unite effectively the expert knowledge of interested parties, who cannot be impartial, with the impartiality of officials who are not sufficiently expert. Tariff battles over certain rates

often result in a compromise between opposing interests, so that they support each other's demands and seem to present a united front, as in the case of semimanufactured and finished products, and agriculture and industry in general. Such a compromise, however, is not necessarily in the interest of public welfare, for it may impose on other branches of industry or on the consumers burdens greater than the profit to the individuals concerned in the compromise. The final decision is made in parliament by political parties who are also influenced by particular interests.

In great industrial nations there have therefore been efforts toward a scientific tariff, to free tariff legislation from political agitation and to substitute a purely factual viewpoint. To prepare such a tariff commissions were established consisting of men who were not personally interested in particular fields of production and who would make unbiased investigations. The scientific method is useful for collecting and sifting material from statistical data and mercantile accounts, but it is not capable of proving positively the necessity of protection and of calculating numerically the height of duties. The United States Tariff Board (1909-12) set itself the task of determining the difference between the costs of production on the same goods at home and abroad for guidance in fixing tariff rates. The present United States Tariff Commission, established in 1916, follows the same policy. Aside from the fact that it is impossible to calculate accurately the difference in production costs, because no two enterprises in the same country have the same costs and because the method of calculation is always variable and open to question, such a method must miss its aim even if every difference so determined led to a correspondingly high protective duty. For this purely private viewpoint may result in protecting every branch of industry, even though the advantage to a particular branch may be more than canceled by far greater disadvantages to other industries or to the country as a whole. Whether and to what extent a protective duty is necessary cannot be determined strictly scientifically but only by a weighing of the economic and political arguments pro and con. It is therefore not a proper province for a non-partisan commission but must be left to the political decisions of legislative bodies. These bodies, of course, should be reformed to meet the ever greater requirements of specialized knowledge.

Like tariff legislation the administration of

customs has more and more adjusted itself to economic rather than to fiscal requirements in spite of the fact that it still theoretically forms part of the finance administration of every state. In former times customs, like taxes, were often farmed out. Now, however, duties are everywhere collected by the state authorities. The organs of administration consist of the administrative service and the supervisory service. The former is concerned with the appraisal of goods and the collection of the legally fixed duties and the administration of accessory services, such as customs warehouses. The supervisory service, administered by a special revenue guard, watches trade along the border and attempts to prevent smuggling. Customs officials also furnish material for statistics of foreign trade and, at ports, for shipping. Neighboring states usually place their customs houses at the same points on the border to minimize the inspections which hinder traffic. They sometimes conclude customs cartels by which they bind their frontier officials to mutual cooperation in the prevention of smuggling.

The duties of officials in the collection of customs vary according to whether the country has adopted specific or a considerable number of ad valorem duties. In the case of specific duties officials must be able to discriminate technically between goods and their many grades of quality; for this purpose extensive testing stations with chemical laboratories and technical apparatus may often be necessary. For ad valorem goods the question is one of ascertaining the market value, which cannot be learned from the article itself but only from contemporary market conditions which themselves are not always self-evident. Prices indicated by the invoices of the importers are not acceptable because they may be wilfully listed at a lower amount for the customs, and the customs officers must therefore arrive at the truth through experts or independent investigations. The United States has its own officials, called appraisers, whose duty it is to keep constantly informed of the actual market value and wholesale price of the goods at the time of exportation to the United States in the chief markets of the country in which they were bought. When the appraised value is higher than the declared, a fine is added to the legal duty. Where the rates on goods differ according to the country of origin, that country must be ascertained, for which purpose many nations have prescribed certificates of origin.

Because of the diversity and indefiniteness of

the commercial nomenclature of goods and because of the continual appearance of new products it is easy for customs officials and the parties concerned to differ regarding the appraisal. A special procedure is usually provided for quick positive decision in such contests, but recourse is usually to the administration rather than to the courts. The chief customs official, who is responsible for final decisions, is allowed to base his decision on the judgment of an expert advisory body, the customs advisers. These decisions regarding the application of certain rates are collected and published to serve as standards for future practise. There may also be doubt as to which rate should apply to certain goods, resulting in a diversity of treatment in the different customs offices of the same country. A merchant in order to be able to base his calculation concerning the possibilities of importation on the actual customs burden may often have to import the particular goods experimentally. Even then he is not sure that the figures so established will hold for future cases. For this reason Germany in 1898 created a customs information service, which has since been imitated by many other countries. Under this arrangement the higher authorities are obliged to issue official information concerning the tariff on goods in answer to all inquiries, to which are attached definite statements regarding the origin and nature of the goods and samples or illustrations. The information is binding on all subordinate officers. A different decision may come into force only after a given period and after time has been provided for official answers to any questions.

The tariffs of different countries vary enormously in arrangement and nomenclature of goods, so that comparison of their rates and the statistical data on foreign trade based on them is extremely difficult. Efforts have therefore been made in recent times to establish a uniform international tariff classification. There are two opposing principles of arrangement: homogeneity of production, especially similarity of raw material (e.g. all articles made from cotton or iron) or of process (e.g. all goods for lathe work); and homogeneity of use (e.g. all clothing, although made of many different materials, or all means of transportation). Similarity of material is usually preferred as a basis of classification, although it cannot be applied absolutely, for many goods, such as machines and toys, are composed of various materials and can only be put in a common category on the basis of their

use. In classification according to material a better account can be taken on the stages of production. This is important because the economic function of customs duties is the protection of national labor, whose employment increases with an increasing proportion of the manufacturing process. The lines between raw materials, semimanufactures and finished products are not sharp, for many raw materials undergo a process in immediate connection with the primary process in order to conserve them, as in the case of hides, or to save freight, as in the case of ores. Again technical concepts do not always coincide with those of commercial policy, for many goods which are technically semimanufactures are treated as raw materials in the tariff when the material from which they are made does not occur in the country concerned and importation in a partly worked state is desirable in order to save freight costs. Such is the case in European importation of copper from the United States. Gold and silver receive special treatment, for they serve chiefly as means of settling the balance of international payments and are therefore everywhere duty free.

As early as 1853 the statistical congress in Brussels expressed the need for a uniform system of trade statistics. As this presupposed an international uniformity in the naming and grouping of tariff items, the International Trade and Industry Congress in Paris in 1889 demanded a uniform scheme not only for the designation of goods for commercial statistics but also for the arrangement of the goods in the tariffs. The *Conférence Internationale de Statistique Commerciale* in Brussels in 1910 worked out a definite statistical classification of goods which combined 1831 tariff items into five different groups of goods as follows: live animals, foodstuffs and drinks, raw materials and simply prepared goods, manufactured articles and gold and silver bullion and coins. The Central European Economic Conference of 1912 in Brussels tried to create some uniformity, for these states at least, in order to facilitate reciprocal treaty negotiations. The World Economic Conference in Geneva in 1927 took the matter under consideration and recommended appropriate action to the Council of the League of Nations. This conference appointed in 1928 a committee of experts who worked out a schedule which consists of 21 sections, 86 chapters and more than 1300 items. The obstacles to the adoption of this schedule are still very great, involving more than mere formalities

Differences in terminology can be eliminated only by more exact definitions, which may involve serious differences from colloquial usage. Problems of more decisive economic significance also enter. A tariff is fitted to the economic conditions of one country and cannot be transferred to another without alteration.

Considerable valuable material is contained in the documents of the International Economic Conference (Geneva 1927), especially Documents C.I. 1, 23, 28, 32, 33, 37, and C.E.C.P. 71 (1).

CUSTOMS UNIONS. A customs union is an association of two or more independent tariff territories to form one customs area, involving the elimination of all interterritorial customs barriers and the adoption of a common tariff policy. Short of a complete merger with the loss of political sovereignty a customs union represents the highest degree of customs rapprochement between independent units. Looser forms of customs alliance are found in most-favored-nation treaties, in mutual preference systems and in reciprocity agreements. It is also possible to conceive of a customs federation having a common tariff policy for its members but allowing them to retain internal customs barriers. On the other hand, a customs union must be distinguished from customs annexation, an arrangement by virtue of which a territory is incorporated in a larger customs area without receiving formal representation in the body determining the tariff policy for this area. Similarly, extension of the tariff of a mother country to a colony involves involuntary customs assimilation.

To be really effective and enduring true customs unions must be based on the elimination of important differences in economic structure, in political and administrative organization and in the taxation systems of the member states; moreover, the authority in tariff matters must be delegated to a superior body and the independence of each member stringently limited. This is feasible only where customs unification is stimulated not merely by economic needs but also by important political factors. In the past the great driving force in the formation of customs unions has been the desire for economic integration of the national territory to provide the economic base of a national state. It was a manifestation of the same force that earlier led to the abolition of internal customs in territories which had already achieved political unity. The German Zollverein is the classic example of a customs union which laid the foundation for a great national state. The experience of South Africa, where a customs union was formed six years before the creation of the political Union of South Africa in 1909, is somewhat similar. In the United States the constitution adopted at the formation of the Union forbade interstate tariffs and provided for a common tariff authority. Both in Canada in 1867 and Australia in 1901 the economic unification of the provinces and states was simultaneous with political federation. On the other hand, where the political situation is unfavorable, the differences between the member states will be reflected in dissensions as to the tariff policy to be pursued, the distribution of revenues to be collected by the union, and similar matters, and will in the end prevent the creation of a customs union or force its speedy dissolution. This has been in part true of the Austro-Hungarian customs union and of the Swedish-Norwegian customs union, dissolved in 1905 with the disappearance of political conditions favoring close cooperation.

The history of the German Zollverein really began at the opening of the nineteenth century, when trade between German territories was hampered by the existence of sixty different customs systems and tariff walls. After the lifting of the continental embargo conditions were made even worse by the appearance of ruinous English competition. As early as 1816 associations of manufacturers had called the government's attention to these evils and asked for remedial measures. Their action led in 1818 to the passing of a new Prussian tariff which

aroused much uneasiness particularly among the smaller German states. It was followed by a series of tariff treaties between Prussia and the neighboring German states. The treaty with Hesse-Darmstadt in 1828 involved the establishment of a Prussian-Hessian customs union. The south German and a majority of the middle German states were alarmed at and opposed to the Prussian policy, so that in 1828 a south German customs union was formed by Bavaria and Württemberg, and in the following year Saxony took the lead in creating the middle German customs union. The formation of the national Zollverein proceeded thereafter very rapidly, as though impelled by an irresistible force. In the period 1828 to 1830 the Prussian-Hessian, the Württemberg-Bavarian and the middle German customs unions joined forces, and by January 1, 1834, customs barriers were abolished throughout most of Germany. While many south German and central German states were driven to join the union by growing economic and financial distress, Prussia was actuated mainly by a political consideration, the desire to eliminate Austria's leadership among the German states. Public opinion in Germany accepted the idea of the Zollverein with great enthusiasm, viewing it as a step toward the long desired German Empire.

The ideologist of the customs union movement was Friedrich List, who publicly advocated the idea of a national customs union as early as 1817. In his classical treatise, *Das nationale System der politischen Ökonomie* (Stuttgart 1840; tr. by S. S. Lloyd, London 1904), he offered a brilliant summary of the theoretical argument in favor of customs unions. List stressed the importance of the nation as a historical, cultural and political entity standing between the individual and humanity, asserted that one of the criteria of a normal nation is the possession of a territory adequate for its economic development and maintained that the modern way of correcting territorial inadequacies, in better accord with law and the welfare of the peoples than the older methods of personal union and conquest, is the association of states based on voluntary bilateral agreement.

Until 1867 the legislative power of the Zollverein was vested in an annual customs conference whose decisions had to be unanimous. Each full fledged member, as distinct from small territories which were represented by neighboring larger states, had one vote. The Prussian tariff of 1818 in a slightly modified form became

the tariff of the union. Interstate trade was made entirely free. The few customs frontiers still left were intended to enable certain states to collect such indirect taxes as could not be made uniform. The member states retained their separate customs administrations, but these were made subject to uniform regulations drafted by a central office in Berlin. The net receipts of the customs houses were centralized and distributed among the member states in proportion to population.

The fact that the decisions of the customs conference had to be unanimous paralyzed the functioning of the Zollverein, because any alteration in tariff policy could be accomplished only after interminable negotiation. This situation was radically changed by the agreement of 1867, which replaced the customs conference by a federal council and a customs parliament, organs respectively of the executive and legislative power. These new bodies were composed of the Bundesrat and Reichstag of the North German Confederation and representative delegations sent by the south German states. Decisions were in both bodies subject to majority vote, but the southern member states still retained the right of veto for certain important cases. The Zollverein persisted in this form until 1871, when it was merged in the new German Empire.

There were several attempts to expand the German customs union into a central European or even a European union. Noteworthy among them was the project of the Austrian minister of commerce, Bruck, who in 1849 suggested the formation of a central European customs union to include the Zollverein, Austria and Hungary.

This union was obviously intended to serve a double purpose: the creation of an enormous free trade area with a population of seventy millions and the securing for Austria of political leadership side by side with Prussia. Bruck's plan was thwarted by Prussia when it concluded a most-favored-nation treaty with France in 1862, a step which brought it in line with the general free trade trend initiated by the famous Cobden Treaty between England and France.

The *Ausgleich* of 1867, which was a culmination of constitutional reforms begun in Austria in 1859, gave Hungary a voice equal with Austria's in deciding upon tariff matters and established a regime of decennial treaties between Austria and Hungary to regulate the tariff policy of the dual monarchy with reference to the outside world. Austria's economic rapprochement with Germany was perforce confined to the sign-

ing of a commercial treaty, and her exclusion from the German customs union was in part responsible for her elimination from the political union of the German states in 1871. The Austro-Hungarian customs union passed through many crises; difficulties were experienced particularly at each renewal of the treaty. Of special importance were the growing opposition on the part of the expanding Hungarian industries and the apportionment of contributions to the common treasury. It is not certain how the problem would have been solved had not the war intervened and brought in its wake the dismemberment of the dual monarchy and the dissolution of the customs union.

In the seventies the rapid shift of the commercial policies of various European nations in the direction of economic nationalism and protectionism caused great anxiety among the free traders and produced a crop of customs union schemes based on the principle of free trade. Prominent among them was the plan offered by the economist Molinari in 1879. It was somewhat similar to the *Union de Midi* of Léon Faucher, who in 1837 vainly agitated for the abolition of customs barriers between France, Switzerland, Spain and Belgium. Impressed by the success of the *Zollverein*, which he considered one of the greatest achievements of the nineteenth century, equal in importance to the spread of free trade policies, Molinari suggested the formation of a customs union which would include France, Belgium, Holland, Denmark, Austria-Hungary and Switzerland. He appreciated the difficulties of such an undertaking but argued that they could be overcome just as the obstacles to the continued functioning of the monetary, postal and telegraph unions had been successfully surmounted. It is certain, however, that Molinari underestimated the importance of national antagonisms in Europe and of class antagonisms within each country. In discussing this plan before the *Société d'Économie Politique*, Leroy-Beaulieu pointed out that it was impracticable because the present generation was not inclined to pacifism and that the experience of the *Zollverein* was not convincing since that union was based on "racial" homogeneity. He maintained that the proposed union, including many different races, would give rise to quarrels and dissensions and multiply rather than reduce the number of factors leading to war. Finally, he laid particular stress upon the difficulties which would arise in connection with fiscal problems. Although Molinari's plan found

favor in certain free trade and pacifist circles in France, Switzerland and elsewhere, the ruling groups even in France were opposed to it. Bismarck believed that the new customs union would adopt protectionist policies and provoke reprisals on the part of England.

Another proposal which received official consideration was made at the 1880 international congress of commerce and industry in Brussels by a German delegate, Kaufmann. He urged the formation of an *Association Douanière de l'Europe Centrale*, which should include the three great powers, France, Germany and Austria-Hungary, and three smaller states, Belgium, Holland and Switzerland. He argued that this union would command a domestic market of from 125 to 150 million population and would be effective in meeting the industrial competition of England and the agricultural competition of America. But neither this proposal nor many others similar in character could be accepted by countries steadily drifting toward a mutually exclusive protectionism.

Other customs unions projected in the eighties were based on protectionist postulates rather than on free trade ideas. Thus agricultural interests sought in the customs union of European countries protection against the growing agricultural competition from overseas. For example, the leader of the agrarians, the Austrian politician Alexander Pezz, proposed the formation of a European customs union in order to induce the United States to grant more favorable terms of trade to European countries. Of a similar character is the doctrine formulated in this period that the United States, the British Empire and Russia constitute three world empires which can be met on equal terms only by a customs union of the other European states.

In the subsequent period the commercial policies of the continental countries were dominated by imperialistic considerations. A policy directed toward colonial expansion and the acquisition of new markets through commercial treaties based on the existence of high protective tariffs left for the time being no room for customs unions. In this period only the agrarians demanded a customs union, but even they used it merely as an excuse to exact higher protective duties on agricultural products. The *Mitteuropäischer Wirtschaftsverein*, founded in 1904, confined itself to urging closer relations through minor measures such as uniformity of customs formalities and the like.

In the same period customs unions were

linked up with imperialist thought in England, where Rhodes and Chamberlain advocated an imperial tariff. They proposed at first a system of imperial preferential duties, hoping thus to pave the way for a commercial union. While the hostility of the British electorate was reflected in the Liberal victory of 1906, opposition to these plans came also from the dominions. They were developing native industries and were little inclined to renounce tariff protection even against the mother country; moreover, customs duties were an important source of revenue to some of them. In the war and post-war periods a system of preferential duties between the United Kingdom and some of the dominions was gradually developed, and in the late twenties a movement for "empire free trade" was sponsored by Lords Beaverbrook and Rothermere. In 1930 the Imperial Conference discussed it as one of several ways for bringing about closer cooperation between the United Kingdom and the dominions, but so far no definite action has been taken.

On the American continent the customs union movement has been connected with Pan-Americanism, or the doctrine of the community of interests of all American countries. The First Pan-American Conference, called by Secretary of State Blaine in 1889, considered among other matters the possibility of a customs union between the United States and Latin America, but rejected the proposal in view of the enormous difficulties involved in the unification of customs tariffs of eighteen states with widely diverging economic structures and political aims. The subsequent Pan-American conferences never considered the question again. Membership of the majority of Latin American states in the League of Nations and the recent interpretations of the Monroe Doctrine by the United States make the possibility of a Pan-American customs union even more remote.

During the war an impressive project for a military and economic federation was developed by Friedrich Naumann in his *Mittleuropa* (Berlin 1915; tr. by C. M. Meredith, London 1916). Naumann's final aim was an economically self-sufficient empire under German leadership extending from Scandinavia to the Near East and encompassing as its main constituents Germany, Austria-Hungary and Turkey, but as a first step he proposed a system of preferences and a customs alliance between the countries involved. In a sense this scheme reflected a shift in Germany from colonial ambitions to the ideal

of a continental empire. Equally far reaching schemes for economic union were being drawn up by the allied powers at the same time. Both plans were to a considerable extent influenced by the war mentality and would probably have proved impracticable even had the termination of the war been accompanied by a restoration of pre-war conditions.

The peace treaties, on the contrary, created a number of new states, whose tariff policies, affected by the recrudescence of nationalism, disturbed the pre-war economic balance of the continent. The customs union projects agitated in this period had in view not so much distant economic goals as the mitigation of post-war maladjustments. In this category belong the *Anschluss* movement in Austria and the plan of a Danube federation to include the territories of the former Austro-Hungarian monarchy. The *Anschluss* movement has thus far been barren of results because of the unfavorable alignment of forces in international politics. The Danube federation seems to be doomed to failure, because in all of the new states nationalist feeling is potentially stronger than it had been in pre-war states and every movement resembling a return to the status quo ante is interpreted as an attack on their sovereignty and political independence.

Wider in scope is the Pan-Europa plan formulated by the Austrian writer Coudenhove Kalergi and based in large part on the old "three world empires" theory. Its advocates urge the union of the continental states as the only way of meeting the rapid economic expansion of the United States and the economic decline of Europe. The movement has scarcely gone beyond the stage of theoretical discussion; its success is doubtful in view of the closeness of economic ties binding many European states to overseas countries and of the wide divergence of the political interests of European states.

More recently the idea of European solidarity was taken up by the French foreign minister Briand, who in May, 1930, addressed in the name of the French government a memorandum to the European members of the League of Nations suggesting the establishment of a Union Fédérale Européenne. He placed emphasis on the political aspects of the union and stated clearly that the economic problem must remain subordinate to the political interests, thus rejecting for the present the idea of a European customs union. During the meeting of the 1930 League Assembly a committee of

European states was created for a further discussion of the Briand plan.

In the meantime the idea of European economic rapprochement found new support in the agrarian countries of eastern Europe. Representatives of the governments of Bulgaria, Czechoslovakia, Estonia, Finland, Hungary, Lithuania, Poland, Rumania and Yugoslavia met at Warsaw in September, 1930, and organized an informal European agrarian bloc. The purpose of the bloc was to bring about close cooperation in matters of marketing and tariff policy and to strengthen the bargaining position of the member countries in negotiating with the industrial countries of Europe for reciprocal tariff privileges.

The League of Nations took manifold action against the economic crises of the post-war years. Its activity culminated in the International Economic Conference at Geneva in May, 1927. The conference did not discuss a customs union but passed resolutions favoring a reduction of customs duties, on which thus far no action has been taken. Generally speaking, reliance for the stabilization of international economic relations has in this period been placed upon the negotiation of commercial treaties aided by such private action as that of international cartels and other associations of producers.

There has been but one new customs union during the post-war years. It was agreed upon by Latvia and Estonia in the treaty of 1927 but has not yet been established. The unification of tariffs and of allied economic legislation provided for in the treaty has proved to be an extremely difficult and slow affair. Latvia has concluded meanwhile a most-favored-nation treaty with Russia and has thus complicated the situation. It is doubtful whether this customs union, which was supposed to take effect in 1931, will ever materialize.

CUSUMANO, VITO (1843-1908), Italian economist. Cusumano was trained by Adolf Wagner in Berlin and became an adherent of the historical school and, with some important qualifications, of the socialism of the chair. He was professor at the technical institute of Palermo and afterward professor of finance at the University of Palermo. The book which established his reputation was *Le scuole economiche della Germania in rapporto alla questione sociale* (Naples 1875). This book, in which the opinions and tendencies of the various Germanic trends were stated with great amplitude and objectivity, opened a new realm to Italian economic thought. It was not merely a piece of exposition but a brilliant critical analysis which aroused much controversy and started the tide of reaction against the dominance of Ferrara, who had been propounding the optimistic doctrines of Carey and Bastiat. Although the author manifested sympathy for the socialists of the chair he observed that such writers generally neglected to designate the limits that state intervention encounters in the interests of the dominant class on the one hand and in the interests of production on the other.

Although his later writings never equaled his first in brilliance or influence they contain valuable historical material and acute observations. In *Diomede Carafa, economista e finanziere italiano del secolo xv* (1870) he was the first to recognize many of Carafa's notable ideas on finance; his *Matteo Wesembecio, scrittore di materie finanziarie nella prima metà del secolo xviii* (1880) and his monograph *Sull'economia politica e la scienza delle finanze nel medio evo* (1876) are collected in *Saggi di economia politica e di scienza delle finanze* (2nd ed. Palermo 1887). He also wrote *La teoria del commercio dei grani in Italia* (Bologna 1877), *Delle casse di ammortizzazione in Sicilia . . . secolo xviii* (Palermo 1888) and an article on the history of the guilds in Sicily (in *Giornale degli economisti*, vol. v, 1890, p. 241-50). His *Storia dei banchi della Sicilia*

(2 vols., Rome 1887-92), which included his work on royal exchange in Sicily in the thirteenth and fourteenth centuries and that on private bankers' bills of Palermo in the fifteenth and sixteenth centuries, is significant not only for the facts revealed but also for the general history and theory of the instruments and institutions of credit and the history of the relationship between public and private banks.

CUT-THROAT COMPETITION is a term frequently used to describe a degeneration of the competitive process which results in widespread selling below cost, in "spoiling the market." The term cut-throat is used to emphasize the element of wilfulness or even malevolence which was formerly assumed to have been an important factor in the adoption of certain competitive policies dictated by the desire to injure and eventually to eliminate rivals rather than directly to advance the fortunes of the concern adopting these policies. The contemporary emphasis is better carried by the phrase "ruinous competition," in which the stress is placed upon the general situation in which losses are inflicted upon the concern initiating such policies as well as upon its competitors. Neither of these phrases is necessarily coterminous with "unfair competition," which is a designation used for a group of competitive practices declared illegal. The degree of overlapping between these terms obviously depends upon the extent to which cut-throat or ruinous competition is outlawed.

There are several reasons for the development of cut-throat competition, particularly for the frequency and severity of price cutting. Theoretically this type of competition is bound to arise in industries of increasing returns when the failure of costs to expand proportionately with output is traceable to the influence of internal economies. Wherever the internal economies of large scale production continue throughout the entire range of effective demand, i.e. for whatever volume of output can be sold at a price covering the marginal cost of production, stable equilibrium is theoretically impossible until cut-throat competition has led, through the weeding out of all but the largest producer or through the curbing of competition by agreement, to the establishment of some

degree of monopolistic control. In this connection perhaps the most important factor is the existence of unused capacity, particularly in the shape of fixed and specialized plants but also in the form of executive ability. Under such conditions it will presumably be to the advantage of a producer to expand his output so long as the additional product can be sold at a price in excess of the prime or direct costs of its production. Where a concern engages in the production of several lines of non-competing goods or services, or where special conditions exist which will permit the restriction of the effects of price reduction to the additional portion of the output, as in the case of dumping on a foreign market or of local or personal price discrimination, the temptation to expand and cut the price is correspondingly stronger.

It was early recognized that these conditions stimulating cut-throat competition are peculiarly prevalent in the field of transportation and local public utilities. It is probable, however, that similar conditions, although their causes may not be so readily discernible, develop in a great many other industries at certain stages in their expansion. Technical progress results generally in increasing the importance of the fixed and specialized plant, and although the ratio of fixed costs to total costs may not be so high in manufacturing industries generally as in public utilities, still the increasing instability and inelasticity of demand with the spread of style and fashion influences make imperative strenuous efforts to maintain a full utilization of capacity, however small the resulting contribution to the maintenance of the fixed plant. Moreover, the existence of seasonal and cyclical fluctuations in demand, coupled with the impracticability of storing output, is partially responsible for the fact that during a great deal of the time industry has at its disposal a capacity in excess of current effective demand. Furthermore, excess capacity is in a sense inherent in every competitive situation regardless of variations in the total demand. Each producer is constantly striving and occasionally succeeding for a time in deflecting a larger than normal share of the whole trade to his products. Since this tends to be interpreted as evidence of increasing favor with the buying public, there results an expansion of plant capacity by each of several competing producers in turn, which is practically certain to be intermittently unused.

Price cutting begun for the innocent purpose of increasing output is usually met by retaliation

from competitors, with the result that the general body of producers or traders is drawn into the struggle. Under such circumstances the reduction of prices inflicts losses upon every concern in the trade, losses which are quite likely to be irreparable for the majority, although they may be only temporary and even eventually recoupable for the lowest cost producer in the industry. The struggle resolves itself into an endurance contest in which the concern with the longest purse is likely to win. In such trade warfare other weapons in addition to price cutting are usually employed. Striking examples are found in commercial bribery, particularly of a competitor's customers, in defamation of competitors and their products, in the provision of auxiliary services, such as repairs, and of supplementary trade inducements in excess of customary standards, such as free delivery. There can be no doubt of the mischievous consequences of resort to the foregoing and similar practises. They tend to make competition privately unendurable and socially wasteful. It is well known that competitive policies of this type have been adopted by combinations which seek to eliminate competitors or force them to join the combination. But it is now generally recognized that their use by so-called big business has latterly tended to diminish, while their employment by harassed and ill managed little concerns appears to be growing relatively more common.

On the whole, however, cut-throat competition is less prevalent now than it was in the second half of the nineteenth century. In some areas, where the tendency toward a degeneration of competition was plainly inescapable and where the social waste involved in cut-throat practises was clearly recognized, amelioration was provided by governmental intervention which permitted the establishment of monopoly under some form of public ownership or administrative control. Over the greater part of the field of manufacture and trade, however, in most modern states private checks have been chiefly relied upon for escaping the evils of cut-throat competition, although these voluntary means, in so far as they are cooperative in character, are generally subject by law to judicial or administrative scrutiny. In the nineteenth century pools and "gentlemen's agreements" upon prices were the most common of these voluntary means. At present trade associations and industrial institutes are the most conspicuous organizations of this type. They

have succeeded to a certain extent in making their function of eliminating ruinous price cutting respectable, but they have only partially succeeded in making price cutting itself disreputable. The methods employed are diverse: education in cost accounting, adoption of uniform basing points for price quotations, interchange of statistical information upon every aspect of the business situation, both for each producer and for the trade as a whole, and the like. Conformity of individual producers to the standards set by the trade is in the last analysis enforced by the lively sense of the need for self-preservation, although measures of coercion against recalcitrant firms are by no means unknown even today.

Private efforts to check the destructive tendency in competition have been generally tolerated by governments because of the advantages accruing therefrom in stabilizing business conditions and in improving the competitive position of a country in foreign markets. By the Federal Trade Commission Act of 1914 the American government has created an agency to exercise public control over destructive competition in trade. The aim of the regulation of business practises by the Federal Trade Commission is not entirely or even primarily to assist business in avoiding self-destruction. But in discharging its function of safeguarding the public against fraudulent, deceptive and predatory practises the commission has brought about an appreciable elevation of the plane of business competition.

CUZA, ALEXANDER JOHN (1820-73), Rumanian ruler and agrarian reformer. Cuza was born in Moldavia of an old landed family. He was educated in Paris and took part in the Rumanian revolution of 1848. In 1859, in the absence of any foreign prince to assume the

office, Cuza was chosen first ruler of the united provinces of Moldavia and Muntenia. His reign was marked by several great reforms. In 1864 he made all education free and elementary education compulsory; in the same year he introduced universal suffrage; and above all, with the help of Mihail Kogălniceanu, he carried through the great rural reform of 1864. Mainly because of the powerful opposition to this rural reform he was forced in 1866 to abdicate and emigrate.

Cuza's rural reform had two distinct aspects: one constitutional, the other economic. Cuza and his friends, filled with the ideas of the French Revolution, aimed to effect the complete legal emancipation of the peasants, most of whom were still bound to the land by servile ties. Likewise, in keeping with *laissez faire*, the landlords were released from restrictions which still qualified their title to the land. The main fight was over the extent of freehold to be given to the former serfs. Since cattle grazing was the chief occupation of the peasants, their new holdings were made to vary with the number of animals in their possession. The new holdings, running between 2.30 and 7.87 hectares, were less than those the peasants had previously farmed. The peasants were also given the poorest and worst placed land and made the victims of many other abuses. Moreover, they paid compensation for the abolished servitudes, but the landlords retained free the surplus land of the estate although by ancient right it was a reserve of the villages. Finally, the peasants were left dependent on the landlords for additional grazing land, for loans in kind or cash, and after Cuza's departure they lost all political rights. Hence the reform marked the emergence of the latifundia, which characterized Rumanian agriculture until 1918, and the depression of the peasants to a state of pauperized freeholders, because its well intentioned makers had subordinated economics to the glamour of legal liberty.

CYNICS. This word, derived from the Greek *κυνικοί* (dog people), is used to describe the school of Greek philosophy founded by Antisthenes (c. 450-366 B.C.), son of an Athenian

citizen and a Thracian slave woman. Many of Antisthenes' followers were of Thracian descent, like Metrocles and Hipparchia; or Asiatic Greeks, like Bion and Diogenes; or Phoenicians, like Menippus; in short "bastards" of that class from which the motion of Aristophanes had recently taken away the full rights of citizenship, to which they could have aspired under Pericles. Antisthenes was a teacher in the gymnasium reserved for boys excluded from the academy and the lyceum because of their mixed or doubtful ancestry. This gymnasium was located near a sanctuary of Heracles, called *Κυνόσαργες* (*Cynosarges*), "dog's wattle," "kennel," because, according to one of several popular legends, here Heracles brought up from the underworld the "shining dog," Cerberus. Antisthenes according to Diocles (Diogenes Laertius, vi: 13) was nicknamed "the simple dog," but the term "dog people" was not popularly used until a disciple of Antisthenes, Diogenes of Sinope, proudly adopted the nickname "dog," first applied in derision to those "bastards" by the well born Athenian boys.

Cynicism, the stern and bitter philosophy of a group of outsiders, was social criticism aimed at shocking all conventions and prejudices of polite society (*épater le bourgeois*). As such it follows the tradition of the sophists, the first to claim a knowledge of economic, social and political science more profound than that possessed by practising statesmen and business men. It was a startling novelty when mere foreigners without citizens' rights boldly claimed the right to criticize because they had devoted thought and reasoning to affairs of state and society. The cynics started a systematic propaganda for the rationalization of all the traditional and necessarily largely irrational relations between men. The stonemason Socrates questioned the professional knowledge of every citizen, including even the self-appointed teachers of the new wisdom. Whatever "gentlemen" (*καλοὶ κἀγαθοί*) had been wont to accept as the self-evident rules of good behavior was now mercilessly analyzed by a few nobodies.

The new intellectualism was skeptical toward the established order of society. The privileges of nobility were regarded as empty by Lycophron, the inequality of freeman and slaves as unnatural by Alcidas, both of them disciples of Gorgias. The small city-state seemed intolerably narrow and narrow minded to these wandering teachers and preachers who felt at home wherever their Greek language was under-

stood or even—like Democritus or Herodotus—wherever they could indirectly communicate with intelligent foreigners—the *λόγιοι ἄνδρες* of all nations. Rivalry between Greek cities as well as local patriotism appeared contemptible to Gorgias; Hippias welcomed all his hearers, Athenians as well as strangers. A world embracing enlightened despotic monarchy like Persia would invite favorable comparison with the mob rule into which the democracy of the petty Greek republics was fast degenerating. The traditional morals, civic usages and proprieties of the cultured Greek “gentleman of independent means” are questioned and criticized by comparing them with the more useful ways of life of the proletarian “banausic” worker and the “happier” and more “natural” life of barbarians and primitives. Antisthenes must have known the Orphic simple life of the Euripidean Hippolytus as well as that of the pious hermits (*εἰσῆται*) of his mother’s Thrace, who lived ascetically in the woods, far from civilization, abstaining from animal food and contact with women. In any case there have always been men unwilling or unable to conform to the exigencies of communal life in society. Like the tramp, or hobo, of today there were in Greece men who fled from the company of their fellows, roaming in the woods like solitary wolves (*λύκων ὄρωσται*) or stray dogs (*κυνῶν ὄρωσται*). Antisthenes’ glorification of a life imitating that of wild animals, Diogenes’ (as well as Rousseau’s) craving for a return to nature and a natural simple life, are the philosophic sublimation of this atavistic asocialism of the lonely hunter, who abandons the pack to fend for himself and to obtain what ages later the cynic philosopher calls the *αὐτάρκεια* of the man who has assimilated himself to the gods by becoming independent (from society) and self-sufficient.

Socrates had taught Antiphon that “to have no wants at all is an attribute of godhead, to have as few wants as possible the nearest approach to godhead” (Xenophon, *Memorabilia*, 1: 6, 10). In a society in which it is impossible for a pauper or a slave to enjoy the pleasures of life reserved for the rich and mighty there is always space for the growth of a consolatory philosophy or religion which teaches the humble that they may become free by liberating themselves from the tyranny of their own lusts and passions or even become rulers by governing themselves according to the laws of virtue and godlike by not wanting what they cannot get. In a luxurious civilization based on manifest

injustice and violence virtue seems to demand that the righteous man should remain poor and turn his back upon all the refinements of culture.

To Antisthenes the primitive natural life of the Thracian settlers, the free roaming through the wilds of the initiates of the Thracian hunter god, Dionysus Zagreus, of the werewolves clad in animal hides and assimilating themselves to the beasts, the adventures of the mythical Heracles with his club and his lion’s skin wandering over land and sea, fighting against the evils oppressing humanity, seemed superior to the cultured ways of men living in enclosed towns. Protagoras in his book on human origins had praised the technical progress made possible through the Promethean invention of fire: the cynic would answer to this panegyric of progress that man had degenerated through the use of fire, clothes and houses, that urban life was the beginning of all injustice, that inventions have made man more miserable than before, and that therefore Prometheus was justly punished by Zeus for starting men on the road to evil.

Ivery object of Athenian national pride—not even excepting the glorious memories of the Persian wars—was reviled by the cynics. To them the pageant of the numerous Hellenic gods and the creations of the great poets and artists of Hellas were nothing but conventionalized fancies, the divinity being by nature (*φύσις*) one and indivisible (although it might have a plurality of ethical attributes) and certainly not to be conceived as similar to any image made by man. The cults of the state were bluntly rejected, the practise of virtue declared to be the only sacrifice worthy of the divinity; prayer was to be resorted to not in order to obtain material benefits but only to secure the help of the divinity in achieving justice. The Dionysiac festivals which had given birth to the glory of Attic drama were called “spectacles for fools.” The athletic beauty of the *καλοὶ ἀγαθοὶ* was belittled as an attribute on which a bronze statue might justly pride itself but not a living being. One isolated concession to the traditional Greek worship of physical perfection was to be found in Antisthenes’ book on love, marriage (polygamic) and the procreation of children, where the rough semibarbarian taught the eugenic principle that a wise man should wed a handsome woman. The cynics recognized no other nobility but that of virtue, no liberty but that acquired through freeing oneself from the tyranny of

one's vices. When about to be sold as a slave Diogenes asked, "Who wants to buy himself a master? The cynic despised wealth and preferred to live as a beggar. For his morose philosophy joy was but a negative phenomenon amounting only to the absence of pain. Sensual pleasure was considered almost as bad as madness. Fame and distinction had no lure for the cynic, who was not afraid of evil repute. Love as a passion for a particular mate seemed unreasonable to Antisthenes, who would "have shot Aphrodite if he could have done it," not content with merely wounding her hand, as the Homeric Diomedes had done. Ridiculing competition for a particular woman's favor he was satisfied with the cheapest prostitute, for whom no other man cared. Even masturbation is defended by Diogenes as a simple and legitimate method of getting rid of an irrational itch; "would that hunger were as easy to assuage," said the Sinopian. As to food, the cynic was satisfied with what nature produces of her own will. He wanted no undergarment as long as he could fold his cloak in two; he needed no house as long as he could sleep under the colonnade of a temple or public building, in a barrel or under whatever shelter he might find. Diogenes thought it foolish that a useless statue should be bought for three thousand drachmas, when two copper coins were the usual price of a quart of nourishing barley flour.

Philosophy itself, that is, all theoretical speculation without immediate practical significance, seemed a useless pastime of rich idlers to these proletarian thinkers. Even in antiquity there were those who said that cynicism was not a philosophy but a mere way of life (Diogenes Laertius, vi: 103). The radical proletarian materialism of Antisthenes, who would not admit as real anything that could not be grasped with hands (Plato, *Theaetetus*: 155E), will be best understood in the light of Lenin's passionate defense of materialism against the subtle "empirio-criticism" of Richard Avenarius. When Socrates confessed that his interest lay exclusively in mankind and its problems he unwillingly turned away some of his pupils from pure science and the joys of disinterested intellectual adventure. While this did not prevent keen minds like Plato and Aristotle from following their own urge for theoretic speculation and scientific research, the heavy intellect of Antisthenes (the "late learner," as Plato called him) clung obstinately to that anticritical attitude, trying to justify it by a curious logical

theory according to which no judgments but judgments of identity can be true. If this were correct it would follow that only tautological statements can be true and that therefore all scientific statements are either truisms or falsehoods. The error consists of course in the supposition that the copula "is" in the judgment "man is good" has the same meaning as in the judgment "twice two is four."

Less primitive is Antisthenes' thesis that a thing, being simple, cannot be defined and that therefore a definition can only be a description of the parts as components of a whole (Plato, *Sophist*, 251-64). Moreover, he denies—thus voicing the earliest distinct expression of nominalism—the reality of general ideas, saying that he could see a horse but not "horseness," thus ignoring the biological reality of the animal type horse, which continually reproduces itself through seminal transmission from one pair of individuals to another. The lost book of Antisthenes on education and names was probably designed to refute the Heraclitean theory that the names of objects—which a child learns to know in the course of his education—are significant of the essence of things and hence to criticize the belief that any real knowledge can be derived from etymology. For Antisthenes the names were obviously just so many proper names of individual things by which to call them, so many conventional handles attached to the objects for an exclusively practical purpose.

Developing in this and other ways the negative conclusions of Socratic dialectics the founder of cynicism disparaged scientific research and learning in order to exalt common sense, moral character and above all the self-denying ascetic endurance of Socrates.

The frequent statements that Antisthenes—although himself a prolific writer—considered even reading and writing unnecessary and dangerous achievements are quite trustworthy, since even Plato thinks that man may have paid dearly for Thoth's invention of the alphabet by a weakening of his memory.

The social and political ideals of the school were expounded in Antisthenes' book *On Law or on the Commonwealth* (*Περὶ νόμου ἢ περὶ πολιτείας*). Under the influence of the Orphic doctrine that men are like a herd of cattle owned by the gods and guided by divinely appointed "shepherds" and "archshepherds" Antisthenes glorified the primeval epoch when, under the reign of Kronos, no states existed and a single

herd of men was tended by sage wardens knowing all human and animal languages. According to the cynic ideal this is the way men should have gone on living, Greeks and barbarians together, united by obedience to one common law, one herd under one shepherd, one flock under one "shepherd of nations," the wisest and most righteous of all men, a state of affairs which Plato (*Republic*, II: 372-73) contemptuously called a constitution fit for pigs only.

The classic exponent of the theory that humanity was not to be divided into Greeks and "barbarians" but into honest and dishonest people is the celebrated geographer Eratosthenes of Alexandria, the pupil of the cynostic philosopher of Chios, Ariston. Eratosthenes remarked (Plutarch, *Moralia*, 328B-329D), that Alexander the Great claimed to have put into practise the project Zeno conceived under the influence of Antisthenes. The publicists of the Ptolemaic Empire were not slow to make use of this argument, and there is no doubt that the policy of Alexander and of the first Ptolemies to bridge the gulf between Greeks and barbarians and to fuse them into one imperial people derived its leading ideas from cynic cosmopolitanism rather than from the uncompromising belief in Hellenic supremacy over all servile nations of Alexander's teacher, Aristotle.

It is a great pity that neither Antisthenes' treatise on law and commonwealth nor Diogenes' *Republic* (Πολιτεία) have been preserved. What is known of the latter is very little: according to the Sinopian no state is worthy of the name unless it embraces the whole world, nothing but the whole world being worthy to be called the cosmopolitan's fatherland. No private property was to be tolerated. Women and children were to be held in common as in Plato's republic.

Most interesting are Diogenes' ideas on money. No gold but only a fiduciary currency consisting of sheep's knucklebones (ἀσπράγαλοι), such as the people used instead of dice for gambling, was to be used in the republic of Diogenes. Such money can be multiplied through breeding more and more sheep or goats, each slaughtered animal yielding four knucklebones. If the number of circulating ἀσπράγαλοι grows through breeding, that is, through increased production and consumption of meat, skins and wool, the exchange value or purchasing power of the single knucklebone will gradually diminish. Thus hoarding will prove

unprofitable. Diogenes, the son of the banker Hikesias of Sinope, had been exiled together with his father, according to Diocles, for having in the capacity of state banker and city mint farmer debased the currency of his native town. This was not of course a case of criminal forgery or counterfeiting, as ignorant interpreters of the text have believed: the death penalty rather than exile would have been the proper reward of such a crime (Demosthenes, XXIV; c. Timocrates, 212-14). It is the typical case of the state banker lending to the community the good silver which it needs for meeting its debts to foreign creditors and obtaining in return the privilege of issuing token money (or semifiduciary currency). The profits of the financier responsible for such an inflationary monetary policy would naturally be confiscated and he himself exiled as soon as the evil consequences of the debasement of the monetary standard brought a deflationist opposition into power. Diogenes seems to have remained a deliberate advocate of a freely but moderately inflated currency without intrinsic value.

Diogenes' ideas on monetary reform are not isolated in that restless epoch of transition. The curious pseudo-Platonic dialogue *Ἐρωξίλας* [ascribed by Suidas (ed. by I. Becker, Berlin 1854, p. 46) to Socrates' pupil Aeschines and obviously connected with the cynic school through its tendency to make a wise and healthy man with few wants appear happier than the richest of the rich] explains the relative and subjective nature of what is commonly believed to be wealth. Starting from the current view that wealth consists in having many treasures (χρήματα) the author discusses certain fiduciary currencies which have no value outside a particular country, such as the officially sealed leather purses of Carthage, with unknown contents, instead of the weighed quantity of gold dust which they were originally supposed to contain. Wealth being defined as that which is useful to (certain) men, the author tries to show that gold and silver are not wealth because they are neither consumable goods nor instruments of production. The specious argument is not carried to its logical conclusion, but the whole conversation is an obvious echo of contemporary propaganda to supplant metallic money by some kind of fiduciary currency.

The *Ἐρωξίλας* also contains an interesting discourse on professional intelligence as wealth, exchangeable against the various necessities of life. This section owes its existence to the dis-

cussions concerning the remuneration of the teachers of wisdom, which was initiated by the attacks of Socrates and Plato against the sophists who offered "wisdom for sale." Thus for the first time in history an attempt was made to define the economic status of the intellectual worker, a modern conception entirely foreign to the aristocratic prejudice of antiquity, which considered salaried work as banalistic, essentially proletarian and unworthy of an educated gentleman. The economic assimilation of exchangeable intellectual services to paid manual work is quite in the line of cynic asceticism, which strives to glorify work and exertion (*trópos*) of every kind, especially disagreeable heavy labor, at the expense of leisure and the illness of the rich. The apotheosis of the restless toiler and wandering philosopher Heracles—the patron saint of the *cynosarges* sanctuary—is the expression of the cynic idealization of the proletarian worker's, the wayfaring intellectual's and the slave's way of life.

Crates was the author of a utopian work, of which we know only the initial verses. A few fragments remain of the yarn of Onesicritus, the cynic steersman who sailed with the fleet of Alexander the Great from the mouth of the Euphrates along the Persian and Karmathian coast to India. Their chief interest lies in the account of the curious meeting between the adept of the moderate intellectual asceticism of Greece and the fanatic self-tormentors of Hinduism roasting their bodies on glowing stones under the paroling rays of a tropical sun in order to accumulate magic virtue or merit with an eye to future rebirth. Even if the interpreter had been more competent, Onesicritus and the *sanyasi* whom he calls Calanus would scarcely have understood each other.

Cynism has been called the philosophy of the Greek proletariat. In reality it expresses rather the thought and feelings of the disillusioned, *bourgeois déclassé*, the "parlor pink" revolutionary in thought but not in action. While the top dog and the under dog are quite naively agreed about the value of the bone for which they are continually fighting, the cynic cares too little for anything but his private peace and quiet to put up a real fight against the existing order of things. Like Diogenes, who asked to be buried on his face because the world would soon be turned upside down, these intellectuals, not unlike modern half-way socialists, aesthetes and quietistic intellectual critics of contemporary vulgarities and hypocrisies, were not really anxious to overturn society; they felt sure it would collapse of itself very soon after their own death. They undertook neither scientific study nor agitation for a reordering of social life but having uttered their protest sought individual liberation each for himself.

Their teaching was tolerated by the Greek and Roman world partly because they supplied that sermonizing, preaching of morals and "soul saving" which the official clergy, concerned only with magic and ritual, cared nothing about. They were begging voluntary missionaries of what they considered truth, justice and virtue, "shepherds" (*ποιμένες*) and overseers (*ἐπισκοποι*). Furthermore, their teaching that poverty and wealth, slavery or freedom, make no difference to real well-being (*ἀδιάρροπα*)—embroidered upon by the stoic school and again and again repeated by the itinerant missionaries of the Christian faith who inherited the hairy cloak, the staff and the wallet as well as the technique of the popular moralizing sermon developed by the cynic preachers Bion and Teles, and finally adapted to the new theology by the "Christian Cynics"—was quite acceptable to the wealthy ruling classes. It answered somehow their own vague discontent with most of the coarse pleasures that unintelligently applied wealth can procure and their longing for real peace, security and freedom. Moreover, it fostered among the downtrodden poor and the exploited slaves the shiftless resignation with their fate and that hopeless absence of social and economic aspirations which Ferdinand Lassalle has so fiercely damned as one of the worst obstacles barring the way to a better social order. The beautiful marble statues of Antisthenes and Crates which have come down to us did not stand originally in a slaves' ergastulum or a worker's house, where nowadays we might find a cheap print of a portrait of Karl Marx, but in the cool parks of a wealthy Roman's Tusculum.

CYRENAICS. Socrates and his disciples did not inquire into how man lived and by what motives he was actuated but into how man ought to live and act in order to be *eudaimon*—literally, to have a good time or a good fate. Their incidental contrast of what the ordinary untaught man actually did with what he ought to do, an unconscious mixture of normative doctrine and descriptive psychology, is characteristic of all ancient attempts to establish a satisfactory theory of values, that is, of motives of human action. Positive and negative values (*αἰρετά* καὶ *φευκρά*), good and evil, were thus not so much what man craves and what he

abhors but what he ought to embrace and what he ought to reject. Thus values were ethical, and ethics is far older than analysis of the mechanism of volition and emotion.

The earliest and nearest approach to a psychological theory of values is in the doctrines of Aristippus of Cyrene (c. 435-c. 365), a pupil of Socrates, and of his followers. His fundamental thesis is that all living beings (*ζῷα*, animals) crave pleasure (*ἡδονή*) and flee from nothing so much as from pain. Thus nature (*φύσις*) testifies that pleasure alone is desirable in itself, all other things being sought only because and in so far as they give pleasure. Aristippus could not ignore the fact that the grim Antisthenes went about protesting passionately that he would prefer madness to pleasure. This he called a mere perversion (*διαστρεφής*). Of the paradoxical but deeply rooted longing for occasional pain (which explains not only self-torture but also the attraction for the "sympathetic" spectator of tragic drama and poetry, bullfights, catastrophes, burial ceremonies and the like) Aristippus gave a wrong but widely accepted explanation, saying that "the lamentations of actors are heard with pleasure, real wailings, however, with pain."

Another curious flaw in Aristippus' argument is that he should assert that all living beings or all animals seek pleasure, thus pretending to know that animals have the capacity for what we call pleasure and pain, when by his own theory (Sextus Empiricus, *Adversus mathematicos*, VII: 195) each man knows only his own sensations. For the rest, Aristippus' method of reasoning is similar to that of his cynic adversary: the animals are set up as models for man, and the natural state of things is supposed to be superior to the perversion made possible through civilization.

The modern theory (C. G. Lange, William James, Hugo Münsterberg, Georg Simmel and others) that emotions—far from being the ultimate motive of volitions—are but the psychological reflections of successful or unsuccessful, appetitive or repulsive, volitional efforts, was unknown to antiquity. Since voluntarist theory of values (wealth being whatever man wants, illth what he shuns) as well as the biological and energetic (thermodynamic) explanations of values (positive value attaching to what furthers life, i.e. adds energy to the living system or helps to avoid loss of energy and vice versa) was inaccessible to an age ignorant of theories of natural selection and the survival of the fittest,

ancient speculation could only oscillate between an emotionalist and an intellectualist theory of motivation. The psychological mechanism of intersubjective sympathy (*Mitgefühl*) was unknown to the Cyrenaics and their adversaries. They could find no bridge between egotistic and the so-called altruistic group feelings, or social emotions. This inadequacy of Cyrenaic psychology was, however, hardly responsible for Aristippus' view of patriotic self-sacrifice as absurd, a wise man's fatherland being the world and his wisdom too precious to be sacrificed for fools. The cynic cosmopolitan, Diogenes, who considered virtue and not pleasure the goal (*τέλος*) of the wise man's every action, would not have been more ready to die for his city than Aristippus. The latter's attitude in this respect is in marked contrast to that of his later compatriot, Synesius of Cyrene (d. c. 414 A.D.), who wrote that it was necessary to defend civilization against the raids of the African savages, and to that of the late Cyrenaic Anniceris, who taught that it was good and sweet to do something for one's fatherland (one wonders whether he would have admitted that it is *dulce . . . pro patria mori*) and even to sacrifice oneself for friends and relations. Yet even he is embarrassed for a hedonistic explanation of such altruistic actions. Curiously enough he admits that such altruistic values cannot be established on a mere rational basis (*λόγος*), but that a habit forming education (*ἀνεθίκεσθαι*) must contribute toward overcoming our egocentric dispositions, so that we may learn to take pleasure in the pleasure of others. This is the nearest approach to an understanding of the psychology of group feeling of which ancient intellectualism was capable.

It should be noted that the Cyrenaic definition of pleasure as a gentle emotion in contrast with pain as a rough stormy emotion somewhat anticipates modern knowledge that pleasure or pain is a function of intensity, of the psychic stimulation, agreement passing into irritation when the intensity of stimulus transcends a certain limit.

Diogenes Laertius (II: 94) attributes to the Cyrenaic Hegesias a remarkably modern relativist statement: "Nothing is by nature (in itself) agreeable or disagreeable; it is rarity and strangeness (novelty) or satiety which make a thing agreeable or disagreeable." The history of art indeed shows a continual search for new, unfamiliar sensations and the sudden rejection of experience grown tedious through too fre-

quent repetition. Hegesias was the first to plead for an effort at understanding criminals instead of judging them. Nobody, says Hegesias, sins of his own free will, but rather under constraint of some passion. He should not be hated but reeducated.

Like the cynics, the Cyrenaics did not care for scientific research or philosophic speculation, because of the incomprehensibility (*ἀκαταληψία*) of physical knowledge. Our senses can grasp only subjective sensations. For these we have names in common (e.g. white or sweet) without knowing whether we all mean the same impression; we know nothing about the things themselves and may be absolutely mistaken about them. We do know our sensations and cannot mistake them.

The Cyrenaics regarded the dialectic art (logic) as useful, one of its most important uses being the destruction of superstitious beliefs engendered by popular religion. The wise man must free himself from the fears caused through belief in supernatural beings. Theodorus, the atheist, taught – as did Socrates' disciple Kritias, tyrant of Athens – that religion is only good to keep the masses in subjection. The wise man, however, is free to do as he chooses; if he wanted to, he could without fear commit adultery, theft and sacrilege. This complete amorality was of course just as purely theoretic as that of Friedrich Nietzsche; Theodorus certainly taught like Aristippus that even if there were no laws the wise man, free to do what he likes, would observe every law, because by acting otherwise he would cause more pain than pleasure to himself.

The Cyrenaics, the right wing of the Socratics, were on the whole just as satisfied with existing laws as the cynics were dissatisfied with them. As members of the ruling class they are obviously conservatives, convinced that the existing social order is the best possible in this imperfect world. It is very characteristic that in order to denote the exact opposite of pleasure all Cyrenaic philosophers contemptuously used the word labor or grind (*πόνος*), so worshiped by the radical cynics. In fact, to know the minds of the beautiful athletically trained Greek gentlemen of the classical age, whose portrait statues were done by Praxiteles and Lysippos, we cannot do better than turn to what the sources tell us about Aristippus, a rich owner of several estates. Wealth, he said, is essentially different from a shoe: it cannot be too large. He earned as much as he could through teaching

and through displaying his wit at the court of Dionysius of Syracuse, telling the wealthiest tyrant of antiquity that he expected to be paid handsomely for what he had to offer. A man of the world with most refined manners and distinguished deportment, he could wear his embroidered purple robe, the rough hairy cloak of Diogenes or no clothes whatever with equal grace and dignity. He delighted in exercise and sports, in the refined pleasures of the table and in those which love—conceived as a high art of flattering all the senses—could offer to men who cultivated their bodies with no less care than their minds. He could not but despise the sorry wisdom of those who define happiness—as Epicurus was to do later on—as the mere absence of pain. The halcyon serenity of Aristippus' genial personality is not of course essentially connected with his hedonism. Hegesias, nicknamed *πενυθής*, although his follower, said that, strive as we may, we cannot attain happiness and therefore life is not worth living.

CZARTORYSKI, ADAM JERZY, PRINCE (1770-1861), Polish statesman. After receiving a thorough education at home and abroad he was unofficially ordered by Catherine II to pro-

ceed to St. Petersburg, where he entered government service and became an intimate friend of Grand Duke Alexander. In 1799 he was appointed minister to Sardinia. Following the death of Pavel in 1802 he was ordered by Alexander to return to Russia and was appointed, first, assistant to the minister of foreign affairs and, two years later, acting minister.

As minister Czartoryski conceived the plan of a European confederation under Russia to be directed against Napoleon and worked for the restoration of Poland and for the free autonomous union of all Christian Balkan peoples under the protection of the Russian emperor. Although he resigned from the ministry in 1806 Czartoryski, still in high office and influential, continued his political activities on behalf of a restored Poland. In 1814-15 he was the principal advocate of an autonomous kingdom of Poland as a part of Russia with proper constitutional safeguards for the rights of peasants, towns and the Jews. In the years 1815 to 1830 he remained the spokesman of progressive conservatism in the Polish senate. With the outbreak of the Polish insurrection of 1830-31 Czartoryski was put at the head of the revolutionary government, but his hope that better results would be obtained through diplomatic intervention prevented him from displaying very energetic action on behalf of the insurrection.

Following the failure of the insurrection Czartoryski emigrated to France. As émigré he remained the recognized leader of the conservative element in Polish society. He was the guiding spirit in all Polish activities, chiefly in 1848 in Prussia, in 1849 in Hungary and in 1854-56 in Turkey. He also acted on behalf of the freedom of the eastern Slavs, the Czechs, the Hungarians, the Rumanians and the Italians, often without success.

Czartoryski held that a reorganization of Europe on the principle of national sovereignty would promote universal peace. Through his followers he also initiated a strong movement for the industrial development of Poland.

CZERKAWSKI, WLADZIMIERZ (1866-1913), Polish economist. Czerkawski taught economics at the University of Cracow from 1897 until his death. He confined his interests chiefly to problems of economic theory, and it was he who did most to familiarize Polish economics with the principle of marginal utility and in general with the theories of the Austrian school. He trained a number of young scholars and raised the professorial chair at Cracow to the position of an important center of theoretical investigation.

Czerkawski's chief theoretical work, *Teoria czystego dochodu z ziemi* (Theory of the net income of land) (Lemberg 1893), shows the strong influence of the Austrian school, from whose premises, however, he has drawn extremely subjective conclusions. Czerkawski understands value exactly as do the Austrians, but his interest is almost exclusively confined to subjective value. Not commodities but their values interest economics; profits and income are to be regarded only as increment values; production is neither the only nor the necessary source of income. He disputes a number of principles of classical economics, such as the equality of profit ratios, the law of supply and demand and the principle of costs, and indicates instances where the subjective valuation may stand in direct opposition to these principles. He criticizes the Ricardian theory of rent, but also disagrees with Bohm-Bawerk in that he regards the distinctions between land and capital and between interest on capital and rent of land superfluous. In concluding he offers a theory that is based upon the combination of the principles of imputation and of lower valuation of future commodities. Czerkawski has not attempted the application of this theory to concrete cases. In economic policy Czerkawski favored the development of the co-

operative movement and unquestionably leaned toward government interference in economic matters.

CZOERNIG VON CZERNHAUSEN, KARL, FRIEDRICH (1804-89), Austrian statistician. On completing his studies at Prague and Vienna in 1828 he entered government service, and in 1841 he became chief of administrative statistics in the Austrian ministry of finance. During the time that the statistical bureau was a department in the short lived ministry of commerce Czoernig held the position of chief government statistician, and before his retirement in 1865 he served for three years as president of the central statistical commission of Austria. From 1850 to 1852 he was in charge of organizing the Central Marine Authority in Trieste, and for many years he headed the department of railroad construction, which was responsible for the development of the Austrian railway system.

As chief statistician Czoernig brought to his office a new conception of the purpose of government statistics. It was to be no longer a mere tool in financial administration but a study of all phases of economic and social life of the country by an independent government agency coordinating the statistical data which had been collected by various departments of the government as a by-product of their work. With this purpose in view Czoernig elaborated methods of collection and scientific presentation of statistical material and established close contacts with other government departments. Where official cooperation was impracticable he relied upon semipublic agencies; in 1844, for example, he submitted questionnaires directly to more than 7000 industrial enterprises—a bold innovation at the time. In 1857 Czoernig drafted and piloted through to enactment the law which reorganized the Austrian population census. Throughout his

career he was in favor of giving the widest publicity to statistical information, and with the widening of the basis of parliamentary representation he began to publish small statistical annuals in addition to the regular bulky source books.

Czoernig also published a number of valuable statistical monographs under government auspices. They include a series of maps showing the geographical distribution of industries in Austria and *Das österreichische Budget für 1862* (2 vols., Vienna 1862), a study which assured him lasting recognition among students of comparative finance. Perhaps his most important work was an ethnographical map of the monarchy completed in 1853 after thirteen years of effort and followed by *Ethnographie der österreichischen Monarchie* (3 vols., Vienna 1857), which represents a portion of a projected comprehensive account of the history and contemporary status of the numerous national groups. His *Österreichs Neugestaltung, 1848-1858* (Stuttgart 1858) also bears upon the statistical study of nationalities.

DAGUESSEAU, HENRI-FRANÇOIS (1668-1751), also known as d'Aguesseau, French magistrate of the reigns of Louis XIV and Louis XV. He was one of the most distinguished of the chancellors who flourished under the French system of *parlements*. Personal elements played a great part in the mode of judicature of the times, and the character of Daguesseau was marked by an extraordinary integrity, sincere piety and irreproachable morality. He could, however, often be weak and vacillating, as is shown by his change of front with respect to the ratification of the bull *Unigenitus*. Daguesseau is considered the first great master of forensic eloquence in France. But he carried his oratorical style over into his voluminous writings, which as a consequence are tiresome. As a magistrate he banished corruption from the tribunals; he was responsible for improving the forms and uniformity of procedure; he was influential in ascertaining more accurately jurisdictional limits. It was, however, through his *grandes ordonnances* that he left his most permanent marks upon French jurisprudence. He took up in detail the great draft of Lamoignon, *Arrêtés ou lois projetées* (1703). Upon the topics which Daguesseau covered he is said to have written in advance entire chapters of the

future *Code Napoléon*. The most important of the *ordonnances* which he drafted may be said to be those on gifts (1731), wills (1735) and entails (1747). His work thus marks an epoch in French jurisprudence and his name ranks with that of L'Hôpital.

The latest and most complete edition of the works of Daguesseau is that of Pardessus (16 vols., Paris 1818-20).

DAHLMANN, FRIEDRICH CHRISTOPH (1785-1860), German statesman, political writer and historian. Dahlmann was born at Wismar and studied at the universities of Copenhagen and Halle. He was made professor of history at the University of Kiel in 1813 and became secretary of the Deputation der Schleswig-Holsteinischen Prälaten und Ritterschaft, defending their rights against Denmark at the diet of the German confederation. In 1829 he became professor at Göttingen, collaborated in the formation of the Hanoverian constitution of 1832 and represented for a short time the university in the second chamber. When in 1837 King Ernst August began his rule by breaking the constitution, Dahlmann was the leader of the seven professors of Göttingen who protested against this violent act. He was deprived of his chair and exiled, together with his colleagues Gervinus and Jakob Grimm, and came in 1842 to the University of Bonn. In 1848 he became a member of the Committee of Seventeen appointed by the diet of the old confederation to frame a constitution, and the product of their deliberations was almost wholly the work of Dahlmann. In the national assembly at Frankfurt he was the leader of the center group, whose ideal was the formation of a constitutional empire under the Prussian hegemony, and he was also a member of the Erfurt parliament of 1850. Disappointed in his political hopes he withdrew to Bonn,

where he devoted himself solely to his academic studies.

Dahlmann's fame rests more on his political influence than on his historical work. His most important work, *Die Politik, auf den Grund und das Maass der gegebenen Zustände zurückgeführt* (Göttingen 1835), reveals him as a typical representative of constitutional liberalism. The English constitution, rooted according to Dahlmann in the old Germanic ideals of freedom, was the best instrument of government and as such worthy of imitation. In his historical works too, such as his *Geschichte der englischen Revolution* (Leipzig 1844; tr. by H. E. Lloyd, London 1844) and *Geschichte der französischen Revolution* (Leipzig 1845), both of which he republished as *Zwei Revolutionen* (2 vols., Leipzig 1853), Dahlmann is most interested in constitutional problems. These works, often referred to as marking the turn from moral to political historiography, are full of severe admonitions to both the governments and the governed. The most voluminous of his scientific works is the *Geschichte von Danemark* (3 vols., Hamburg 1840-43), which carried the story as far as the Reformation. It is vigorously written and is a good example of the philological-critical method.

DAHIN, FELIX LUDWIG SOPHUS (1834-1912), German jurist and historian. Dahn was a professor of law at the universities of Munich, Würzburg, Königsberg and finally at Breslau, where he remained from 1880 to 1910. He taught and wrote on commercial law, German legal history and the philosophy of law.

Dahn belonged to the contemporary historical school of jurisprudence and held that every culture develops its own system of law which can be understood only in terms of the economic, social and other cultural conditions which gave rise to it. This legal philosophy is most clearly expounded in his brief article on the growth and character of law entitled "Vom (über) Werden und Wesen des Rechts" in *Zeitschrift für vergleichende Rechtswissenschaft* (vol. II, 1879-80, p. 1-10; vol. III, 1881-82, p. 1-16). He denied the natural rights theory of law and emphasized

an opposing concept, namely, that the two elements which determine the law of a nation are the national characteristics and "the complex of historical conditions in space and time" which tend to modify them. He refused to restrict jurisprudence to the classical systems of Roman and German law and insisted that the only differences between early law and that of modern epochs were those due to historically different conditions, a concept in line with the theories of Bernhöft, Georg Cohn and Josef Kohler, who in their *Zeitschrift für vergleichende Rechtswissenschaft* tried to formulate a universal history of law on modern ethnological and sociological bases.

Dahn's works on the history of law were, however, of more permanent significance than his rather unoriginal studies in legal philosophy. The most important of these historical works is the *Die Könige der Germanen* (12 vols., Munich 1861-1909), a vast mine of information on German-Roman history and governmental organization to the break up of the Carolingian Empire. It is particularly valuable for the legal history of that period.

A profound nationalistic sentiment pervaded all Dahn's writings. He repudiated cosmopolitanism and insisted that individuals could be classified only in national groups. He held that nationalism was instinctive and defined the state as the unification of a national group for the protection and development of its law and culture. Dahn's philosophy marks him as one of the scholars who strengthened German nationalistic trends, especially in connection with the new German codes which were established after the war of 1870.

DAIL EIRANN. *See* IRISH QUESTION; LEGISLATIVE ASSEMBLIES.

DAIRY INDUSTRY. Dairying is one of the oldest of industries and has existed in some form in most parts of the world. In some instances, as among a number of African tribes, the entire culture of a people has centered around their cattle, whose economic use was primarily for supplying milk and as draft ani-

mals. Butter and cheese making existed at least as far back as 2000 B.C. Until recent times, however, dairying has been primarily a family or tribal enterprise for local consumption, although some products reached more distant markets. Butter and cheese were generally produced by handicraft methods at the place of milk production; some cheese was made in neighboring caves. The growth of large cities and numerous improvements from the sixteenth century on in breeds of cattle, in cattle feed and in various dairy implements prepared the way for the development of the modern dairy industry.

Dairying in America as in other countries was for a long time a family enterprise rather than an industry. The keeping of cows, like the vegetable garden, was merely a part of a self-sufficient family economy. As agriculture passed out of the pioneer stage there was an excess of dairy products over family and local requirements. An outside market was sought for these products, and as there were very few large city markets in the United States which could absorb the excess production, foreign markets were sought. But the low quality of the product was a serious drawback: a great quantity of butter shipped from America to the English market in the early part of the nineteenth century was used not as a food but as a grease for machinery.

It was not until the 1870's that any real work was done toward the improvement of the quality of American dairy products. During this decade the United States Department of Agriculture gave serious attention to methods of handling milk and cream upon the farm and to the manufacture of butter, and soon the dairy industry became an important branch of specialized American agriculture. About the middle of the last century a few butter and cheese factories were started here and there; by 1880 the local cheese factory had practically displaced cheese making on the farm, and during the next two decades butter factories or creameries were started in almost every important dairying community. This shift from farm household to factory production in the United States is indicated in Table 1. Although as much as 30 percent of the butter produced in 1926 was still farm made, most of it was consumed on farms and did not get into the main channels of trade.

Similar shifts between farm and factory occurred late in the eighteenth and early in the nineteenth century in most of the important

dairy regions of Europe. The increased productivity of the factory played an important part in the change from raising cattle for meat to dairying in Europe, America, Australia and New Zealand. At the same time the factory was needed to develop dairying and to make it more profitable when the newer grain and cattle regions of America began to compete with the older agricultural sections and a shift to intensified agriculture became necessary.

Instead of placing milk in pans for the cream to rise the farmer now uses a mechanical separator which not only gives a better product but assures the separation of all the butter fat from the milk. The Babcock cream tester perfected about 1890 enabled the farmer to determine the exact fat content of his product. In the factory machinery has been developed to perform practically every process in such a way that high quality products are almost universally assured. Increased chemical knowledge has changed a great deal of cheese making from a traditional rule of thumb procedure to a scientifically controlled, standardized manufacturing process. The technical scientist has provided also a means of safe and quick transportation and a means of storage which is not only cheap but also preserves quality.

The different phases of the dairy industry are characterized by various types of organization. On the farm relatively small scale individualistic units generally on a family basis dominate milk production. There are not many exceptions, however, particularly in production for city use, and organizations of farmers have exerted an important influence even in this

phase of the industry. Cow testing and bull associations have played an important part in increasing production in most of the leading dairy countries. The purpose of the former is to select the best producers and eliminate unprofitable cows from the herd on the basis of tests made and records kept by an expert employed by the association; the purpose of the latter is to improve the breed. In Denmark there were 1038 cow testing associations in 1924 with 394,181 cows under test, nearly a quarter of all cows in the country. Much has been done by similar associations in the United States during the last few years to improve the quality of dairy cows and to increase the production per cow, which has been low in comparison with that of other countries. There were 1143 dairy herd improvement associations (formerly called cow testing associations) with more than 500,000 cows under test in 1930; and the average production of cows in testing associations was approximately 7500 pounds, or more than 50 percent above the average for the country. In several countries of Europe and in New Zealand a large number of dairy farmers purchase their implements and feed through co-operative societies.

The creamery and the cheese factory are typically small establishments having few workers, although there has been a decided tendency toward larger units, as in the case of centralizers which collect milk or cream from considerable distances in sparsely settled regions. In the case of butter factories there has been a marked increase in horse power used per establishment, as is indicated for the United States in Table II. A number of factories are owned by individuals or corporations to whom the farmers sell their milk or cream outright. In some instances, as in the case of the Chicago meat packers, large corporations have owned a chain of creameries; and in other cases proprietary creameries have formed combinations. The cooperative, however, is the outstanding feature of the industry. In the United States, for example, 2100 of a total of 3715 creameries of all types in 1927 were cooperative, and the cooperative creamery is of even greater importance in most of the other leading dairy countries. The cheese co-operative is not quite as prevalent. In most cases the cooperative factory manufactures into butter or cheese the milk delivered to it by the local farmers, who are its sole owners, and sells the product to dealers. Profits are divided among members in proportion to the milk they have

delivered. In a more elementary and less frequent form of cooperation the manufactured product is returned to the farmers in proportion to the milk they have supplied. This is merely an outgrowth of the cheese rings that appeared in the United States during the first half of the last century, in which each farmer of a community in turn made his neighbors' milk into cheese on the farm.

Although well organized local cooperatives afforded savings in manufacturing to dairy farmers most of them were weak as marketing organizations. To meet this problem federations of dairy cooperatives or cooperatives having numerous creameries or cheese factories were developed to increase the farmer's bargaining power and secure higher prices for him, to widen markets and to improve, grade, standardize and advertise dairy products. Among the most outstanding cooperatives of this type are the Land o' Lakes Creameries, Incorporated, which has about 450 local creameries, mostly in Minnesota but scattered from Michigan to North Dakota, and which attempts to sell a standardized brand of butter directly to jobbers and to chain store companies; the National Cheese Producers' Federation of Wisconsin and the Tillamook County Creamery Association of Oregon, which together handle about a tenth of the total cheese production of the United States; the Federal Danish Cooperative Butter Export Association; and the New Zealand Producers' Association, which markets dairy products as well as imports requirements and dairy machinery. The All Russian Union of Dairying Cooperatives (Maslocentr) claimed 6175 affiliated cooperatives with a membership of 1,437,400 in 1928 and along with its affiliated cooperatives manufactured and marketed the bulk of the country's butter and cheese and marketed most of its milk, rationalized and mechanized numerous creameries, spread agricultural knowledge, supplied its member cooperatives with machinery and started to prepare the way for collective dairy farming. A further extension of marketing cooperation exists in the federations of cooperative societies for the export of butter, especially in Denmark, the Netherlands, New Zealand, Soviet Russia and Finland, and of cheese, especially in Switzerland.

Between the cooperative and the individual or corporate form of dairy organization are joint stock companies with cooperative features. These are particularly important in the United States. They differ from the usual cooperative

in that a stockholder need not be a patron, the capital stock is divided into equal shares and the members usually cast one vote for each share of stock. Farmers are paid for their milk or cream on delivery, and profits are divided on the basis of stock held.

Cooperation to improve conditions in the industry has not been limited to the producers. There have been many trade associations in the manufacturing and distribution phases of the business for the purpose of gathering trade statistics, analyzing operating statements, consideration of trade policies and the handling of trade disputes, which have brought great advantages not only to those engaged in the industry but to the public at large. These trade associations are the agencies whereby the dairy industries can meet with the farmers' cooperative organizations, which act as representatives of the producers, for consideration of mutual problems. Another organization which serves the entire dairy industry is the National Dairy Council. It does scientific research in the field of nutrition and works with medical, educational and other organizations for the improvement of health. This organization was founded in 1919 in the United States and similar work is being carried on in other countries. The primary object of the Dairy Council is to popularize the importance of an adequate use of dairy products and thereby improve the public health and increase the sales of dairy products.

The American and Canadian country cheese boards on which a considerable amount of cheese was formerly sold deserve special notice. They included cheese factory salesmen and cheese buyers or dealers; the latter had restricted privileges and generally had no vote. The boards declined when more cheese was sold off the boards than on them and when quotations could be established only with difficulty.

In contrast to butter and cheese the bulk of condensed, evaporated and powdered milk is manufactured by corporations. Cooperatives have generally been unsuccessful in this field except in a few instances where a number of cooperative condenseries have combined to sell their products. With increased mechanization and the growing need for expensive machinery and for quantity production the ownership and management of condenseries have passed from proprietary units and small corporations to large corporations. In a number of instances, however, condenseries and creameries merely manufacture the surplus milk of large urban milk

distributing companies; and in some cases condensed milk is a side line of ice cream or butter manufacture. In ice cream manufacture also the trend has been toward large scale production under the domination of corporations. Ice cream plants are frequently controlled by city milk distributing companies.

In the United States dairying is the largest single branch of agriculture with the exception of raising livestock for slaughter. It is estimated that the annual value of its products is almost \$3,000,000,000. The percentages of the total milk production of the country utilized for different purposes in 1926 were: butter 36; cheese 3.5; condensed, evaporated and dried products 3.8; ice cream 3.7; fresh milk for household use 46.7; fed to calves 3.3, wasted 3. The size and growth of factory production in the leading branches of the dairy industry, other than milk supply, are indicated in Table II.

Governments all over the world have given aid to the dairy industry in the improvement of technical processes, in the marketing of

products and through tariffs, bounties and stabilization plans to increase the price to the producers. They have also set up certain quality standards pertaining to dairy products. In practically every dairy country there are some governmental grades upon which butter and other dairy products are sold and prices quoted. In the United States these governmental grades were instituted in 1925 and have superseded exchange or board of trade grades. The regulations pertaining to quality and grades have protected the consumer in the same manner as the pure food laws, and in most instances the primary purpose back of these regulations has been to afford such protection and to place competition between manufacturers and dealers upon an equal basis.

Regulations pertaining to the care and handling of cream and milk on the farms have been promulgated for the purpose of assuring the best quality products. Most fluid milk markets and many market areas for manufactured products have regulations pertaining to the methods of handling milk on the farm and in the manufacturing plants. In many instances these regulations touch even the actual delivery of the products: dairy products, for example, are required to be kept in refrigerators in retail stores.

Some governments have passed laws pertaining to competitive practices and trade agreements. In the United States it is unlawful for sellers to make agreements which are considered to be in restraint of trade. These laws apply to the dealer in dairy products just as to dealers in other classes of goods and are for the primary purpose of protecting the consumer against undue price enhancement and the small business unit against extinction. In some countries, however, agreements between dealers to maintain prices are legal on the theory that profits should be assured to dealer and producer.

From a production standpoint the dairy industry in the various countries can be compared on a basis of total production, number of dairy cows and yield per cow. In 1930 the United States had approximately 22,500,000 dairy cows on farms. This number is exceeded only by India and Russia. On a basis of milk yield per cow the United States' yearly average was estimated in 1930 as 4600 pounds. This average is exceeded by that of practically every dairy country in the world; the highest average, almost ten thousand pounds, is that of the Netherlands.

The importance of the dairy industry in the

national life of a people, however, cannot be measured by the total number of dairy cattle or the total production of dairy products but rather by the percentage of the people engaged in and dependent upon it. The dairy industry is from this standpoint most important in the Netherlands, Switzerland and Denmark. In certain sections of the United States, particularly in the heavy cheese and butter producing regions of Wisconsin and Minnesota and the fluid milk areas surrounding our large cities, dairying holds a similar position.

The importance of dairying and dairy products to the national life can be measured also by the per capita consumption of dairy products. The annual per capita consumption of whole milk varies from approximately four tenths of a gallon in Japan to eighty-four gallons in Finland; that of butter from two and eight tenths pounds in Italy to thirty-four pounds in New Zealand; and that of cheese from one and eight tenths pounds in Chile to twenty-four pounds in Switzerland. The annual per capita consumption of these products in the United States is estimated to be as follows: milk fifty-five gallons, butter eighteen pounds and cheese four pounds.

The international trade in dairy products gives some indication of the relative importance of the dairy industry within various countries. Denmark, New Zealand, Australia and the Netherlands are the leading exporters of butter and cheese, while Great Britain and Germany are the largest importers. The United States is the leading exporter of condensed and evaporated milk; Canada, Switzerland and Australia also export considerable quantities.

In Australia, one of the leading butter exporters, the dairy farmers are operating under what is called the Patterson plan to stabilize the price of butter. Just how well this plan or any other plan will succeed is uncertain in view of a heavy world production. It is quite probable that any scheme which aims to fix prices at levels not justified by market conditions will tend to fail, just as the British rubber control and the Brazilian coffee valorization plan have failed.

The dairy industry should have as its goal two fundamental things; a decrease in cost of production and an increased consumption. The cost of production can be decreased at two points: on the farm through use of better cows and better feeding methods, which will give increased production per cow or a decreased cost per unit; and in the marketing and process-

ing phases of the dairy industry, where there are several possibilities of decreasing costs. Better roads and more efficient trucks will reduce the transportation cost; improved technique in manufacturing will reduce manufacturing cost. Selling costs can be reduced through the tempering of competition between various operating units, which entails a heavy expense for the maintenance of salesmen, advertising, solicitors and expensive sales campaigns. If the public demands the safety of competition it will have to continue to bear its expense. If competitors could make agreements relative to competitive practices, selling costs would be greatly reduced. There seems to be very little danger that the public interest would be impaired under such a procedure, provided there were some public agency to regulate competitors.

From the standpoint of public interest an increased use of dairy products is one of the most important problems before the industry. This is true because an ample use of dairy products is vital to health. Nothing should be done in the producing and marketing of dairy products which would tend in any way to limit consumption. An increased consumption can be brought about by educating the public con-

cerning the value of dairy products and by certifying the agencies of production and marketing in such a way that prices will be sufficiently low to enable the consumer to purchase ample quantities.

DALHOUSIE, TENTH EARL AND MARQUESS OF, JAMES ANDREW RAMSAY (1812-60), British statesman and colonial administrator. Dalhousie showed conspicuous ability on the Board of Trade in the midst of the transport and commercial revolutions of the 1840's. As head of "Dalhousie's Board," a pioneer advisory and regulative department, he waged a losing

struggle, in a period dominated by laissez faire tendencies, for government regulation of railway construction and operation. This achievement and the Indian connections he had through his father, who had been commander in chief in India, and his influence with Wellington marked him early for Indian responsibilities. From 1848-55 he served as governor general of India with the avowed mission of stimulating "material and moral progress." Such acts as those securing to persons who had been converted from Hinduism full rights as citizens, sanctioning remarriage of Hindu widows and instituting plans to provide native education along western lines represented innovations in the traditional Indian social structure which were entirely consonant with British public opinion. Equally startling to India and welcome at home were Dalhousie's economic measures: the introduction of the penny postal system, the encouragement of such public works as irrigation and the inauguration of a vast program for railway and telegraph construction. The main lines of railway development in India were outlined by Dalhousie in a famous minute, and it was due to him that the policy of government guarantees of invested capital, with close supervision of construction and management, was adopted for the railway companies.

Dalhousie's administrative energies were unexpectedly turned to political problems which culminated in tremendous annexations of territory to British India. This territory was gained on the frontiers when the second Sikh war led to the conquest of the Punjab, the Burmese war to the seizure of Pegu and the Crimean War suggested the foundations of the British protectorate in Baluchistan. Dalhousie did not invent, but he provided the principal applications of, the "doctrine of lapse," whereby in the case of seven dependent states the government was taken over by British India in default of heirs to the native rulers. He rewarded prolonged misgovernment in Oudh with deposition of the ruling family and annexation. The sepoy revolt, which broke out soon after Dalhousie's retirement, was attributed by many to his excessive zeal in these instances. It is probable, however, that his political acts served chiefly to fan into a flame the smoldering conflict of cultures involved in his program of alterations in Indian institutions.

Dalhousie possessed many traits common to the Peelite school of statesmen, such as industry, devotion to duty, a high sense of political honor, a masterful disposition, a pride of place and a

readiness to assume responsibility. In these traits and in his policies for India may be found early anticipations of the collectivism and imperialism of the succeeding generation of British statesmen.

DAMAGES are dollars and cents won by an encounter at law. The loss or injury for which compensation is exacted may be irreparable; it may be so personal or vital that a pecuniary equivalent is unthinkable. Yet the simple device of righting wrong by the payment of money has a reputable use almost as comprehensive as the domain of human control. It has a place along with the offering of life or liberty or property in appeasing the gods, removing the guilt of sin and expiating the offense of crime. It is employed as an agency of discipline in a host of voluntary associations ranging from mystic cults to business enterprises. In the law it variously serves the ends of atonement, retribution, vindication, punishment, example and compensation. Its meaning in common speech has been converted into a technical term; a tangle of processes and standards make up a complex, developing and not too clean cut law of damages.

Among primitive peoples, generally at least, the redress of grievances was direct. The kin group was the unit in social organization; the responsibility for personal conduct was collective; the misdeeds of the fathers were visited upon the children. The dominant principle of the blood code was the *lex talionis*, an eye for an eye, a cut for a cut, a bump for a bump. Among many folk—the Kaffirs, the early Semites, the tribes of South Africa—there was a long list of

offensive acts for which the relatives of victims demanded a return in kind. The kindred ideas of atonement and restitution were extended from persons to valuables; an injury to chattels was to be made good by the destruction or the replacement of an equivalent property. The expiation of harm by blood was sanctified in religious rite; it survives in the sacrificial death of the god, the mystery of the Eucharist and the doctrine of the vicarious atonement.

A significant event in the emergence of law was the commutation of blood into money. The elders in folkdom, aware of the cost of protracted strife and indecisive result, little by little established more peaceful methods of composing differences. The feud was subdued into an expiatory combat with an umpire and rules; blows were replaced by a public exchange of expostulations; parties came to wage their laws with compurgators, who were clansmen armed with oaths instead of weapons. The principle of equivalence found a less bloody application in a system of fines applied to petty offenses and extended even to wrongful death. There came into being long catalogues of assorted wrongs, each with its own *wergild* set against it. In comprehensive tables the detriments were often graduated according to the age, sex and caste of the injured; nor was the ability of the wrongdoer to pay left out of account. The invention and extension of the device of composition by money brought the duty of seeking satisfaction within the realm of order.

The quest of damages has marked out the path of the law. As claim followed claim in endless succession, crude agencies of adjustment became courts; private bargaining was subdued into a due process of law; and the magic of ritual gave way before judicial inquiry. In the course of legal events causes involving personal satisfaction came to be affected with an interest to the community, gradually the public and the private concern with forbidden conduct were distinguished, and from a common source with realms which overlapped, the law of crime and the law of tort took their separate ways. The state in the cause of order undertook to punish and to prevent acts fraught with peril to society; in its code a life continued to claim a life, major offenses imposed the loss of liberty and only minor breaches of the peace were to be wiped out by fines. The courts in the settlement of personal quarrels were powerless to restore injured parties to their former positions or to undo what had been done; they were compelled to

resort to compensation in righting wrong, making good loss and appeasing outraged feelings. Rights are nominal until they are challenged and courts accord or refuse recognition. The substantive rules are the secretions of a process of procedure. In the civil and the common law alike the code of damages is the product of continuous litigation.

As folk usage through the Roman code has become the civil law, ordeal has given way to inquiry. The lingering formalism has been detached from the trial of the issue. The evidence is taken in advance, the proceedings are simple and relevant, the arguments of counsel are brief, the record contains only a few typewritten pages, the liability and the amount of the verdict are decided by judges. The discretion lies largely with the trial court; if there is appeal the whole case is retried. The officers of the court are appointees, learned in their trade, skilled in the art of mediation, "free from the obscure sentiments and prejudices" of the laity. It is their task to apply to the changing permutations of fact called cases a few simple and clean cut principles of law. The rule that "everyone is liable for the harm which he does, not only by his wilful acts but also by his negligence or in-advertence" approaches strict liability. It is softened in its application by the interpretation of its general terms and by rules relating to actions which may be maintained and the ways by which they are to be pressed forward to judgment. The measure of damage tends to approximate actual loss. In the civil law the matter of damages may be reduced to a few dominant principles and a multitude of specific holdings; it contains little of intermediate generalization.

In the common law a rational way of decision has only slowly emerged out of trial by combat. The appearance of witnesses in open court, the art of examination and cross examination, the office of judge as umpire, the reference of issues to the jury of laymen for decision, the recourse to an appellate court because of error, and kindred rules of the game attest a surviving spirit of conflict. The rite and ordeal, out of which law has emerged, long left their mark upon process and pleading; the correct performance of a ceremonial without misuse or mistake was essential to an efficacious result. The rigid set of rules applicable to injury and satisfaction was stubbornly accommodated to the flexible demands of justice. As ordeal gave way to law, there were at first lawful awards without substantive rules for damages, since liability and compensation were

wholly within the discretion of the jury. The lawyers, overzealous to make testimony serve causes, came to be restrained with rules of evidence. The judges, sensing the need for a measure of order in a chaotic task, won control over the mechanism of trial and laid down a few simple rules by which the facts of particular cases were to be judged. A claim was established if the wrongdoer had acted wantonly or had been negligent or was to be charged with fraud. But such general words are themselves rather terms of judgment than objective marks; each of them demanded translation into more specific and relevant language. The sequence of specific acts which made up conduct and the circumstances called "the facts" did not easily lend themselves to legal labels. The judges were compelled to expound and to apply their rules; and in exposition and application new rules of a more detailed character emerged. In the course of trial by law—in the complaint and demurrer, in the clash over the admissibility of testimony, in the instructions to the jury, in the disposition of the motion for a retrial—the judge was compelled or found opportunity to make his rulings. As from the lips and pens of a myriad wearers of the ermine ruling followed ruling, the discretion of the jury was limited, the province of the judge was marked out and the primitive rules of wantonness, negligence and fraud were elaborated into a mighty and complicated code of damages. In time the appeal courts in ruling upon prayers for reversal because of error came to impose a veritable body of rules upon trial courts. The developing law of damages is all of it a communal creation of a continuing bench.

The law of damages in tort has the intricate character of the human stuff out of which it is made. The catalogue of wrongs comprehends bodily injuries, wounded feelings, departed affections, impaired reputations, losses of life and a wide assortment of harms to property. These arise from personal brawls, family quarrels, trespass, the collision of motor cars, industrial accidents and the everyday course of business; they are to be attributed to conduct in which malice, negligence and blind chance are variously blended. The concern of it all is either the human wear and tear incident to the activities of an everyday world or luckless happenings which come in the wake of muddled behavior; it is not easy to discover for such items a legal common denominator. The conflict of testimony, which is not unusual, makes the facts uncertain; the motives back of unfortunate occurrences are

not to be read as in an open book. The categories used to comprehend acts—wantonness, malice, negligence, fraud; reasonable precaution, foreseeability, last clear chance; *vis major*, act of God—are catholic zones of tolerance and intolerance. The use of such concepts as duty, fault and cause in an attempt to rest liability upon a non-arbitrary basis makes decisions plausible rather than helps them along. Where judgment is beyond dispute, the recitation of the appropriate rule is enough to dispose of the case. Where the applicable principle is uncertain, fault or cause or duty as well as liability is in doubt; the law and its non-legal basis have to be determined together. At every step in the development of the doctrine by which responsibility for industrial accident was gradually shifted from the employee to the employer the courts recited "no liability without fault"; although in official language the terms were connected by a "therefore," they changed their meaning together. The resolution of issues by judicial combat, the activities of ambulance chasing lawyers, the abuse of expert medical testimony, the swearing to the other fellow's hurt and the purposive tactics of attorneys whose fees are contingent upon success have left their imprint upon the law.

Accordingly, the judicial commutation of wrongs into moneys bears the flexible marks of an institution developed out of conflict. The loss for which pecuniary satisfaction is sought must be real, not hypothetical; certain, not speculative; immediate, not indirect. It must be a consequence of the harmful act of the wrongdoer. The conduct of the person who sues must be untainted by such legal fault as will make him responsible; his recovery is not to extend to losses which might have been avoided or to consequences which might have been averted. An injury to possessions or to purse demands the pecuniary equivalent of restitution; an injury to person calls for adjustment by a scheme of rules beset with historical survivals, reasonable standards and imputations of responsibility. A person aggrieved by a wrongful act of little consequence may appeal for vindication and claim nominal damages. A victim of bodily harm or of fright or anxiety attended by physical consequences may have in lieu of satisfaction compensatory damages. If the act of which complaint is made is reprehensible, there may be added exemplary damages. Such awards—a testimony to the lingering use of private law to serve a punitive purpose—are not unknown in cases

involving assault, trespass, nuisance and deceit; they are common in actions based on slander, libel, seduction, malicious prosecution and false imprisonment. A distinction between general damages, which may be claimed because of the depraved character of the injurious act, and special damages, which must be proved in the particular case, cuts athwart the whole subject.

The state quite consciously may make a private action in tort the instrument of a public purpose. It may by legislative act make the wrongdoer liable for actions or practices which it seeks to prevent to the extent of double or even quadruple the amount of the actual damage. The statutes of various states have permitted compensation to two, three or fourfold the amount of the injury for such offenses as embezzling money from a deceased person, the negligent setting of a fire, malicious prosecution, forcible entry and detainer, the receipt of deposits by the officials of an insolvent bank and discrimination in charges by railways. The federal government in an attempt to increase the hazards of monopoly has provided in the Sherman Act that anyone "injured in his business or property" by an illegal restraint of trade may "in addition to the cost of the suit" recover "threefold the damage by him sustained." The actions which have been brought are not free from uncertainties; harm consciously contrived is in a going society not easily disentangled from the vicissitudes to which business enterprise is subject. In its application the provision is not limited to competitive business establishments; the most notorious judgment in the history of the act has been an assessment of triple damages in favor of employers against the members of a labor union. The provision for a multiple of damages may be a substitute for or a supplement to criminal prosecution.

Apart from tort, especially in the more modern branches of the law, the subject of damages invites a simpler statement. In cases arising out of contract the issue is much less clouded with imponderables. If the penalty for infraction is denominated in the bond—and is within the limits of legal recovery—the judgment is clear. Claims are to be allowed for the value of the use of an article, for a difference between contract and market price, for a loss incurred or a gain prevented by a failure in performance. But if the agreement is not in writing or there is no provision against the contingency or untoward events befall, the courts proceed as if there had been a concurrence of minds and set up as a

standard for default "what was in the contemplation of the parties." The bother comes from such attending circumstances as the non-delivery of machinery and a stoppage in production, the failure to fill orders and a loss of customers, the delay in discharging debts and an impairment of credit. In suits involving infringement of patents the way of recovery is marked out by such concepts as "savings by the use of the invention," "profits in sales" and "reasonable royalties"; in litigation over trademarks compensation is awarded for the value of the custom wrongfully taken away. In the taking of property for public use or by eminent domain an award of damages is no more than the naming of a price in a forced sale. In all such instances the rules have a verbal precision, the judge exercises authority and the jury possesses a circumscribed discretion. But the law is not yet so standardized as to make the facts of no account or to deny to resourceful attorneys the use of strategy.

For the measurement of damages the courts have been able to contrive only approximate standards. The range of injury to person and to property is limitless; the incidence of wrongful act is not easily disentangled; the end of the mischief may lie in the unknown future. In the prevailing social order the domain of the pecuniary calculus is still a narrow one; where best established its way of computation is inexact; the bench and box must work with different degrees of precision at their miscellaneous problems in commutation. The process yields its most definite results in appraising standardized goods for which there is a ready market and a stable price. It is most capricious in assessing personal injuries; harms lie beyond the frontier of the money economy; a measure for depreciation of body, mind or repute is not yet to be had. The readiest guide, capacity to earn, is applicable to only a fraction of the cases; in the instance its full yield to the individual is less than his total loss; in the aggregate it constitutes a far heavier burden than can be imposed. In the heat of combat it is impossible to keep related matters away from the jury; in collision cases damages are invariably higher if it is known that an insurance company rather than the reckless driver is the real defendant; a corporation pays more for its tortuous acts than an individual. The unseemly conduct of the plaintiff may be pleaded "in mitigation of damages." In suits in tort damages were once said to be "at large"; in spite of the power of the bench to set aside verdicts which are plainly inadequate or plainly excessive

and the oversight of appellate courts, standards at least for the immediate future must continue to be in the making.

The institution of damages is not proof against the impact of a developing culture. The devices of accountancy are helping appraisal along from guess to approximation. The resort to commercial arbitration permits escape from outworn rite and a more direct attack upon the issue. The compensation of industrial accidents has been recognized as a necessary cost of production; statutes have replaced the common law; standard rates have been set down for classified injuries; the subject has passed from torts to administrative law. A beginning has been made to compel motorists to carry liability insurance; proposals for vehicle accident compensation are being introduced in many legislative bodies. The good old custom of dealing at arm's length is gone; in the current structure of markets many intermediaries connect the maker and the user of a ware. As a result privity of contract no longer covers the transaction; the action is tort and the device of third party beneficiary permits consumers to sue negligent manufacturers. As corporations plan for a more distant tomorrow, waste, delay and uncertainty make of damages a more and more inadequate remedy. In a business system which must keep going there is an increasing resort to equity to enjoin wrongful conduct and to compel specific performance. As conditions change, the remedies of equitable relief and pecuniary compensation are remade, the fields of contract, torts and administrative law shift their frontiers and the law newly performs its appointed task.

Here as in other of its domains the theory of law is not quite in accord with the fact. It affects to settle disputes on the basis of established principles; it contrives to adapt its standards of judgment to a changing necessity. There is an absence of hurry and a lack of neatness; a constructive task is performed with a backward look—but that is the way of the law.

DANA, CHARLES ANDERSON (1819-97), American newspaper editor. He brought to American daily journalism a greater personal culture than perhaps any other man excepting William Cullen Bryant and Edwin L. Godkin. In 1841 Dana was one of the founders of the Brook Farm Association. He was in Europe during 1848 and wrote a work (republished as an introduction to Proudhon's *Solution of the Social Problem*, ed. by H. Cohen, New York 1927) introducing the philosophy of Proudhon to America and forecasting the necessity of revolution to compel "the bourgeoisie . . . to live by their own labor." His radicalism waned, however, during the period in which he was employed by the *New York Tribune*. After quarreling with Horace Greeley he resigned and became an assistant secretary of war, chiefly to report confidentially to Lincoln and Stanton on Grant's habit of drinking. In 1868 he became editor of the *New York Sun*, with which his name is usually associated. Dana opposed slavery expansion but fought the abolitionists, was an enemy of labor unions and especially of strikes, but a supporter of Kossuth. In American party politics he was an independent whose next move was always unpredictable. He helped write Grant's biography for a campaign document but often assailed him as president. He was complaisant for years about Tammany graft but in the end helped bring about Tweed's downfall. He fought Hayes and Garfield, Cleveland and Blaine. Yet despite his vacillations and cynical attitude his journalistic influence was marked. He encouraged good reportorial writing and trained a group of noteworthy authors. Godkin of the *Evening Post*, disgusted with the crime, suicide and scandal which were Dana's original contribution to American journalism in the *Sun's* columns, often berated him editorially, and their bickerings led to the *mot*, famous in that day, that the depravity of New York City was due to the fact that "every morning the *Sun* makes vice attractive, and every night the *Post* makes virtue odious." Behind the epigram was at least this truth, that the *Sun* was a success and set a style copied by many American papers. Dana was the author of *The Art of Newspaper Making* (New York 1895) and, with George Ripley, of the *New American Cyclopaedia* (New

York 1858-63) as well as of the revised edition (1873-76).

DANCE. The dance is an externalization of emotional energy by means of muscular movement. It is practised not only by men in every degree of civilization and culture but also by many types of animals, especially birds. Its purpose may generally be said to be the expression of concepts and experiences that transcend the rational means of expression of the particular individual.

Sometimes the dance is performed for the sake of its effect upon the dancer himself and sometimes for the sake of its effect upon the onlooker. In the former case it functions as a form of auto-intoxication, whether this end is deliberately sought or is merely an incidental result. Its purposes in this connection may be divided roughly into simple play, sex stimulation, the production of religious or other ecstasy and escape from emotional distress.

Where the effect upon the onlooker is the objective, the process is kinaesthetic Movement is the most elementary means for the expression of emotional states and follows naturally and without conscious effort upon conditions of pleasure or pain in varying forms and degrees. The mental or emotional state of the dancer is translated, deliberately or impulsively, into movements which when perceived by the onlooker arouse in him sensations of muscular sympathy, and these in turn associate themselves through memory with mental or emotional states which have or might have produced similar muscular effects in his own experience. Thus ideas are conveyed from the mind of the agent to that of the spectator through kinaesthesia. The object of dances performed before an audience may be the transference of aesthetic images, the simple conveying of information, the excitement of sex impulses or the establishment of a relationship between the individual and the group, whether of superiority or of unity.

In all these cases the dance differs from the muscular activity of play and simple practical accomplishment by assuming a form, based fundamentally on rhythm with its concomitants, such as accent, repetition, contrast, for the transmission of an inner feeling. With the development of this aspect of form aesthetic elements are introduced which lead the dance away from purely individual and social considerations into the field of art.

Physiologically dancing serves two somewhat different purposes. On the one hand it is a vent for excitement, and on the other hand it actually stimulates excitement. This has led to some confusion especially in considering the extent of sex as a motive for dancing; for while there are undoubtedly numerous illustrations of such motivation it is nevertheless true that since sexual impulses are excited by dancing, many dances that have their origin in other sources are attributed erroneously to this cause because they have led eventually to sexual indulgence.

This confusion arises especially in the consideration of play dances. The major function of play, whether in man or in animals, is to discharge a surplus of energy. Periods of particular gaiety are common to most animals, as well as to young men, and find their outlet in vigorous physical activity. In birds, because of their natural physical buoyancy, this is more marked than in mammals and is also more easily observable. W. H. Hudson describes elaborate dances performed by the lapwing, penguin and scissortail both on earth and in air, involving group activity and regular figurations. Similar dances are common to penguins, ostriches, pheasants, plovers, stilts and even to various species of insects and fish. These manifestations are not confined to the mating season, although under the added excitement of sexual impulses they reach a higher degree of vigor and perfection of execution. Similarly, men have enjoyed play dances from the earliest times. Often, as in the case of the corroborees of the Australian aborigines, their conclusion is orgiastic, for the dance can be said to be inherently the root of the orgy, the sexual act itself being in the nature of a dance. These results, however, are not the motivation of a large class of dances which are sometimes considered to be of sexual beginnings.

Courtship dances are undoubtedly motivated by sex and are an almost universal practise. Among the Australasian tribes they are found

in varying forms with the one common characteristic that it is the men who dance and the women who watch. Frequently the dancers give competitive exhibitions of skill in handling the spear and other weapons, and the women select the ones who please them most. North American Indians in many instances have been found to use similar methods. The function of the dance in these cases is not only to give expression to sexual impulses but also to excite them, both in the dancer and in the onlooker. Dancing as a means of sexual selection was recognized and consequently both attacked and defended down through the Middle Ages and even into modern times.

Among activities designed primarily to stimulate rather than release energy may be cited the production of frenzy which has made dancing a part of the practise of many religious sects and their votaries. The mad bacchantes of ancient Greece and the whirling dervishes of the East are common illustrations. Priests and prophets of many savage tribes and even of more civilized peoples have danced themselves into delirium in order to induce possession by their particular deities, and in these states of frenzy have delivered their oracles. Frequently the ability to accomplish this type of ecstasy has been the test of priesthood. It is found among the Bororos of South America, the sect of Russian dissenters known as Khlysti, the mediumistic shamans of the Turanians and in present day America among the Shakers.

This power of dancing to produce auto-intoxication of an extreme sort has been applied also to other than religious ends. In periods of great personal or communal stress, due perhaps to plagues, famines, revolution or other calamities, the dance has been resorted to, on the one hand to provide violent diversion and on the other hand to cause through its excessive indulgence a state of unconsciousness.

In primitive society dancing plays an important part in every phase of activity. The advance of civilization has so largely displaced the necessity for dancing as a vital practise that it is in fact to primitive groups that we must turn to find its full value exemplified. Among primitive men the mystery surrounding all natural phenomena gave rise to tribal celebrations of every event of any importance in the life of the individual and of the group as an affair of religious as well as of social moment. These celebrations were frequently accompanied by rituals of protection or dedication as well

as by ceremonies of purely tribal significance and personal expressions of joy or grief. That these rites should have found form in dances is entirely logical, for even the most natural movements, when backed by intense feeling, assume larger dimensions and stronger stresses and, as the outgrowth of a particular purpose instead of merely generic excitement, slip naturally into rhythm and form.

It is difficult to make any narrow divisions in these dances between those which were religious and those which were social and occupational, for the lines were apparently loosely drawn in the minds of the men themselves. Their chief concerns were the problems of maintenance and increase, and these prompted their dances as well. Agriculture occupied a large share of their attention and made a basis for the mimetic dances of daily activity which were a popular source of entertainment. But the mystery of growing things involved magic and religion, and agricultural fertility related itself at once to sex. We see this combination of motives clearly illustrated in the agricultural worship of Cybele and Attis in Asia Minor and in the Dionysiac rites of Greece. It is equally a problem to separate those dances which affect the individual from those that affect the group, for there is an inevitable effect upon the individual even in a dance which is chiefly of group concern, and those dances which deal with the individual bear directly upon the life of the group as well. Thus in celebrations of birth, healing, puberty, circumcision, marriage and death the participation in simultaneous movements for a common purpose by others than those immediately concerned tends to establish solidarity. Some dances, largely processional in nature, have as their specific object the parading of strength and the establishment of respect for authority; but even in those designed for other ends the unification of the group is made habitual in the minds of its members by communal dancing.

In certain ceremonials which concern the individual the social aspect is more marked than in those mentioned above. For example, the dance at the ritual of initiation, which invests the initiate with the full rights of maturity, bears closely on the affairs of the group. So does the ceremonial celebration which restores a member to full fellowship after a period of tabu for disease, childbirth, mourning or the like.

Initiation ceremonies in addition to their

avowed purpose also serve a secondary purpose in some cases, as in the *boras* of the Kamilaroi of Australia and the rites of certain Bantu tribes. They include dances of a pantomimic nature designed to teach the youths to abstain from homosexual practises. It is likely, however, that the purpose is not wholly moralistic and that the occasion is seized upon as one of license. In the case of girls there exists the custom in many tribes of a dance at the celebration of puberty in which the young dancers are instructed in sex matters by the older women.

Initiation rites belong also to secret societies as well as to society in general. The Orphic mysteries which arose in savagery and extended into Greek civilization, the Eleusinian and Cabiric mysteries, the Mithraic mysteries of Rome, all involved induction by ceremonial rites and dances. Relics of these practises, devoid of dancing, still exist in modified forms in connection with freemasonry, Roman Catholic and Jewish confirmation rites, ordination of priests and profession of nuns.

One of the most universal types of dancing with group significance among primitive peoples is that which accompanies labor activities requiring unity of action. In nearly all savage tribes there grew up the office of a presultor whose business it was to demonstrate and set the pace for joint movement enterprises. It is perhaps significant of the relation which has always existed between religion and dancing that the presul, or bishop, of the church got his name from this word, which means simply leader of the dance. The practise of working to rhythmic beating or chanting in order to achieve greater unity and efficiency of movements has been very general through the centuries and is widely prevalent at the present time. An obvious example is to be found among the Negro laborers of the southern United States, who slip quite naturally into a sort of dance with improvised vocal accompaniment under a leader in all their joint labors. Malay and Polynesian boatmen are also especially skilful in working together by means of movement to a common rhythm.

The dance serves a similar practical purpose in matters of warfare. War dances not only constitute a popular form of entertainment but serve at the same time to crystallize group solidarity and, in the absence of formal military organization, to provide training and drill for actual fighting. In the time of a campaign their major function is to stimulate the warriors to

a high pitch of courage and excitement, in which the fear of death is made to disappear from consciousness as far as possible. Here, however, as in so many other cases, there is also the admixture of a strong element of religion or magic. The violent demonstrations of the dancers are partly directed toward frightening the enemy after the manner of an incantation. Also, after hostile engagements have been concluded, dances are frequently performed, as among the Arunta of Australia, to frighten away the vengeful ghosts of the enemy dead. There are of course martial dances of victory and, of a quite different nature, intertribal dances of peace at the conclusion of warfare. War dances are found among all savage groups whose existence depends upon success in battle. Outstanding examples are the North American Indians, the Dahomans, the Kaffirs, the head hunters of Ceram, who always send a company of fantastically dressed Jakalele dancers ahead of the fighting line, and the Maoris, whose war dance is especially terrifying.

Such dances as those just mentioned, in which magic is invoked to destroy antagonists, are also employed against less tangible forces of opposition such as drought, barrenness and pestilence. In French Guinea dancers armed with weapons and agricultural implements perform dances which are designed to ward off evil spirits hostile to the crops, and similar agricultural ceremonies of protection and defense are found on every hand. Frequently such dances as these take the form rather of processions than of dances in the stricter sense of the word.

The procession has apparently the same two functions more or less all over the world: on the one hand it serves to protect the object which is encircled in the march, and on the other hand it is able to cause its destruction. The protective aspect of the procession is seen in such instances as the Panathenaic procession of Athens, "beating of the Bounds" and the mediaeval Maypole dances; and it seems probable that the circling of the walls of Jericho was an example of the destructive purpose. Among the Chinese elaborate processions with both music and dance are conducted to frighten away the cholera. In ancient Rome the Salii, priests of Mars, performed a violent dance to dispel the forces of blight and infertility, and similar colleges of armed priests existed elsewhere in Italy. The Luperci made an annual circling of the Palatine hill wearing goatskins

and striking with thongs all the women they met to insure fertility and easy delivery. The *Perchtentanz* of Salzburg, performed every ten years or so, is a relic of the primitive dance of placating a hostile deity. It is performed by men exclusively, some of them wearing elaborate and costly headdresses and accompanied by partners dressed as women, and others, wearing hideous devil and animal masks, who fight and scream throughout the dance. The bells worn by English morris dancers were originally for the purpose of frightening away evil spirits.

In general, these dances are mimetic in character, for it is a cardinal principle of ancient magic that imitation has a supernatural power. The enactment of a situation in mimicry is believed to have the power to bring that situation into being. Evidences of this are found in a great number of dances of different sorts. In agricultural dances the rain and the sun are invoked mimetically, and phallic symbols are carried in processions and dances to insure fertility. It is also a practise in hunting dances to affect the prospective prey by imitating its movements. Similarly mimetic dances are performed before or around the totem to promote the propagation and welfare of the species.

The faith of the savage in these dances to propitiate angry deities or to destroy hostile men or influences probably arose from his realization of the effect of dancing upon himself and his observation of its effects on others. The question of distance from the objects to be affected did not enter into his consideration, for the whole process lay in the realm of the unknown and mysterious.

It is natural that death should be surrounded by elaborate rites and dances. Indeed, the funeral procession still retains a part in the social customs of the modern western world as well as in the more ritualistic parts of the earth. Among primitive men funeral dances were generally performed for the welfare of the departed spirit and for the protection of the survivors from evil influences. Many of the ceremonials were mimetic and were intended to influence the dead by sympathetic magic. Sometimes the dead man's outstanding accomplishments were reenacted for the benefit of the survivors, and pantomimic fights and rope pullings were performed over his grave. The return of the spirit was a possibility greatly feared, and consequently every precaution was taken to prevent it. To this end the Arunta of Australia perform

a wild dance, wearing elaborate headdresses and carrying weapons with which they beat the air to drive the spirit away from its former habitation and into the grave. The earth over the grave is then stamped securely into place. Similar stamping dances are found in Guiana. In the funeral processions of the Roman nobility the dead man and all his ancestors were represented by persons resembling them in stature and wearing wax portrait masks.

Marriage is a cause for much dancing of a different character, largely concerning itself with sex practises and fertility. There are also dances of welcome to visitors, celebrations of peace, of the change of season and of numberless other events. But the dancing of primitive men was by no means confined to special occasions. It constituted the major part of his recreation. Whether even these purely pastime dances can be separated from ritual significance, however, is a question; for the life of the savage was not divided into clearly defined periods of labor and of play but was more unified, with everything related to the two problems of nature, maintenance and increase.

Pastime dances are largely mimetic and except for those which are designed for sexual stimulation usually recount past experiences or look forward to future ones in battle, the hunt or other daily practises. Among warlike peoples the war dance is the chief amusement. The Dahomans almost invariably introduce a representation of the great tribal custom of decapitation. The routine occupations, whatever they may be, are the basis for pantomimic dances. The primitive man seems to take a special delight also in animal dances of as great accuracy as possible. Those dances which deal with more personal problems provide an emotional release not only for the dancer but, through kinæsthetic sympathy, for the onlooker as well and are the root of both the art dance and the drama.

In some of the dances where sex is involved the men dance alone, as in the courtship dances; in others the women dance alone; and in a few instances both sexes dance together. Frequently in the women's dances a sarong is wound and unwound about various parts of the body to emphasize its lines.

In all primitive dances music of some sort is an inseparable feature. It is employed by the dancers themselves, either in the form of clinking ornaments or of clapping and stamping to accent the rhythm of the movements

Frequently singing is added to intensify the expression of feeling or even to tell a story. These and other methods are employed also by the onlookers as a vicarious participation in the dance. In its natural form this music is essentially rhythmic and non-melodic.

In the dancing of primitive society are to be found all the elements of the dance, and civilization has only modified them without adding anything basic. Because it is the most elementary medium for the expression of the perception of life, it is natural that it has declined in social importance with the growth of more intellectual means of expression. As a matter of fact its history is the history of this decline in every direction except that of art. The survivals, however, are numerous even in contemporary practise. Especially in religion has the dance retained its place to a large extent. This is true in both eastern and western religions except those which have grown out of the Reformation.

The Israelites employed dancing in their religious as well as their secular practises. Certainly the dances of the virgins of Shiloh were part of a religious festivity. In orthodox Jewish congregations religious dances are still performed to some extent, as at the feast of Simhat Torah. Dancing was used extensively in the worship of the Greeks and Romans. About the ninth or tenth century in India there arose a larger Hindu temples. Ceremonial processions and dances form an important part of the rituals of the Chinese and Japanese. In both the orthodox and Roman Catholic churches processions still retain their importance, and in some cases actual dancing is performed. In the cathedral of Seville, for example, the dance of the *seises* is performed by boys before the high altar three times a year.

In spite of this persistence in the church the dance has always been subject to censure by religious authorities because of its sexual implications. This censure has been by no means confined to the Puritans, against whom it is usually held as an indication of particular narrowmindedness. The papal decretals forbade clerics to witness mimetic performances because they usually dealt with love. In the Buddhist period in India the Brahmans were not allowed either to see dancing or to hear music, for both were considered devices of the prostitute. In earlier civilizations non-clerics, among them Cicero and Juvenal, frequently inveighed against

dancing. Its practise was closely associated with prostitution, and the lowering of the standing of dancers was accelerated by the rise of professional dancers in civilizations where social dancing was not generally practised, as for example in Rome and the East. From this professional class, however, although it was involved as both a cause and an effect in the ostracism of the dance, developed the art of the theatrical dance, which reached a high state as a more or less individual art in the pantomimes of the Roman stage.

In the fifteenth century, with the rise of the court ballets in which the nobility participated, social dancing was again restored to favor. The first recorded ballet was performed at Tortona in 1489 as a celebration of the marriage of the Duke of Milan. Catherine de' Medici later introduced the custom into France, and for many years rulers vied with each other in the splendor of their productions. In France the dancing period reached its climax in the reign of Louis XIV, who was an enthusiastic patron of the art and a skilful dancer himself. During his reign his ballet master, Beauchamp, made a number of important innovations. He adapted the *branle*, as it was danced in Pontou, to court use under the name of the minuet, and he introduced women into the ballet. He was also responsible for the formulation of the five positions which have remained the basis of the ballet technique ever since. When the king withdrew his patronage, as he did in later life, the dance again became a social outcast and was taken over by the theater.

The countryside had never ceased to dance. It continued to celebrate the same occasions that had inspired the savages to dance, and celebrated them in fundamentally the same way. Ceremonial dances were often repeated and handed down long after their original meaning had been forgotten. While the court dances, because of the elaborate costumes and accoutrements of the nobles, were necessarily formal and stately, the country dances were not bound by such conventions. Kissing was a popular feature of many folk dances, and they were generally lively, sometimes boisterous. Little by little these folk dances had found their way into the court, modified sufficiently to give them dignity and to make possible their performance in court regalia. As the development of an age of artifice, courtliness and graceful manners the dance at this period was naturally an extremely artificial manifestation. It was

related to the surface of living rather than to reality, as it had been in its earlier manifestations. The modern theatrical dance, then, has grown almost entirely from this beginning. Since its premise was manner and not matter it languished with the decay of superficial courtliness. Its continued existence has depended upon the battle fought by all its greatest leaders to restore its essential vitality.

Noverre, in the middle of the eighteenth century, bent all his efforts to the perfection of the *ballet d'action*, a form which made pantomime of more importance than technical display. Noverre's purpose was to relate his art once more to the inner rather than the outer life. On the strength of his reform the dance was revived for almost a century. Delsarte, in the nineteenth century, felt a horror for gestures that had no meaning, and although his crusade for genuine expression was carried on in the field of the drama it was of considerable value to the dance. Isadora Duncan threw aside entirely the basis of the dance as it was established in the court of Louis XIV and built up a new creed, the cardinal principles of which were largely those of primitive dancing. Mary Wigman has carried the reform even farther and has restored music to its original relationship with dancing, that is, to the position of an auxiliary.

The new movement in the dance, which is entirely a product of the present century, has found a strong foothold in Germany and the United States. Its object is not only to develop new theatrical forms but to restore dancing as a social element to its former position. The decreased significance of the social dance today has developed naturally from the tendencies of all civilizations to relegate matters of sex and courtship to privacy. Moreover, dancing as a community feature has become less necessary with the development of a mechanized era in which distances have been reduced and daily life has begun to entail a much closer association of people than ever before. Because the dance is so intimately related to human experience it feels very quickly changes in habits of thought and reflects its period with great fidelity. Thus increasing freedom in the relations of the sexes has been paralleled by increasing freedom in dance forms. The embrace of the waltz caused consternation at the end of the eighteenth century, the turkey trot of 1912 had the same effect, and the introduction of western ballroom dancing into Japan, where men and

women had never before danced together, has created a considerable problem there. The professional dancer has met with a succession of similar difficulties, from the shortening of the ballet skirt by Camargo early in the eighteenth century to the introduction of barefoot dancing by Isadora Duncan at the beginning of the twentieth. The "lay dance" movement in Germany, which has a large following, restates the theory of Isadora Duncan that everybody should dance, and teaches those types of movement which are native to the individual, instead of sets of traditional steps and figures. Rudolf von Laban has been a pioneer and leader in this movement.

The teaching of dancing, which had as its earlier function the inculcating of courtliness in the bearing of individuals in social life, developed into a more independent profession when the ballet lost its royal patronage and was forced into the theater. Through the many years since then it has provided a livelihood for teachers fitted to prepare dancers for public careers and to make social dancers proficient in the popular forms of the day. With the modern movement, however, the range of the teaching profession has been greatly increased. "Lay dancing" has created a large element of amateur art dancers, comparable to the long accepted element of amateur singers and pianists. The dance has also been recognized as an aid to health and physical culture, and has been introduced into many general educational systems. The profession of dancing, including both teaching and public practise, has attained not only considerable proportions but also a degree of economic solidarity. At present it has both local and national organizations for collective action and "trade" publications in the United States and in most of the countries of Europe.

DANIELSON, NIKOLAY FRANTSEVICH (Nikolay-on) (1844-1918), Russian economist. Danielson was born in Moscow. He studied in St. Petersburg at the Commercial Institute and the university and became a bookkeeper in one of the banking institutions of that city. He attracted attention as the first translator of *Das Kapital*, the first volume of which appeared in Russian in 1872. In the course of his work Danielson established personal contact with Marx and Engels and for years remained their correspondent on problems of Russian economics (see *Die Briefe von Karl Marx und Friedrich Engels an Danielson*, Neudrucke marxistischer Seltenheiten, vol. iii, Leningrad 1929).

In his *Ocherki nashogo poreformennago obshchestvennago khozyaystva* (St. Petersburg 1893; French translation, *Histoire du développement économique de la Russie depuis l'affranchissement des serfs*, Paris 1902) Danielson supplied the socialistic Narodniki party with an elaborate theory of Russian economic development. He claimed that Russian capitalism would destroy the natural peasant economy and yet remain without any possibilities of successful development and that Russia would thus pass from a natural peasant economy to some form of socialistic economy without going through an intermediary stage of completely developed capitalism. His argument was based on the assumption that the course of economic development in the period 1861 to 1891, marked by the rapid growth and impoverishment of the rural population and by the imposition of heavy taxes on the peasantry particularly burdensome because of falling agricultural prices, constituted the general law of Russian economic evolution. He differed from Vorontsov, another eminent representative of the Narodniki, in that he underestimated the power of the Russian peasant economy to withstand the inroads of capitalism, and he aroused the criticism of Russian Marxists of the revolutionary orthodox wing as represented by Plekhanov and Lenin

as well as of the evolutionary revisionist wing as represented by Struve when he denied the potentialities of Russian capitalism. His analysis did not appear convincing to Marx and Engels nor was it borne out by the subsequent economic development. The period between the publication of his work and the beginning of the World War witnessed the increase of peasant holdings and a rising economic standard of the peasants which provided a market for the products of large scale industry.

PETER STRUVE

DANIELSSON, AXEL FERDINAND (1863-99), Swedish journalist, popular leader and pioneer of socialism. As a young student he assisted the tailor August Palm in the publication of the newspaper *Socialdemokraten*. In 1887, after Ijalmar Branting became editor of this paper in Stockholm, Danielsson went to Malmö, where he launched the newspaper *Arbetet* and assumed leadership of the labor movement in southern Sweden. As an inspiring popular speaker and as an eloquent and brilliant writer he was loved, feared and respected. For his antiparliamentarian agitation and ruthless onslaughts upon the existing order, particularly upon the courts of Malmö, he was sentenced to eighteen months' imprisonment. After this experience Danielsson inclined toward Branting's less radical policy of parliamentary tactics and in 1893 and again in 1896 was elected to the Riksdag.

Danielsson was an irreconcilable enemy of the anarchistic tendencies in the party. As early as 1888 he had outlined a Swedish socialistic program. Not until 1897, however, did the party adopt a program of its own, drawn up by Danielsson, who on the basis of the Erfurt program of 1891 worked out wholly independent formulae. Being something of a Bohemian Danielsson did not always come up to the requirements of the dominant forces in the party and too often met with misunderstanding and hostility. But he was idolized by the working class. He early attained a maturity of mind that

would have borne him forward as party leader and representative in the Riksdag if his life had not been cut short. He established for himself a permanent name in the Swedish social democratic and labor movement.

GIRHARD MAGNUSSON

DANILEVSKY, NIKOLAY YAKOVLEVICH (1822-85), Russian scientist and journalist. Danilevsky was a student of ichthyology and made outstanding contributions to Russian legislation on fisheries. His *Darvinizm* (2 vols., St. Petersburg 1885-86) summarized the anti-evolutionist arguments known at the time and met with a pamstaking refutation at the hands of several Russian scientists. In the work for which he is best known, *Rossiia i Evropa* (appeared in 1869 as a series of articles in *Zaria*; published in book form in St. Petersburg 1871, 5th ed. 1895; tr. by K. Notzel as *Russland und Europa*, Stuttgart 1920), he developed a theory of cultural-historical types, first formulated by the German historian Heinrich Ruckert and resembling the later theories of Oswald Spengler in *Untergang des Abendlandes*. A cultural-historical type, according to Danilevsky, is a race or family of nations, closely related by obvious linguistic ties, which has so rich a spiritual endowment that it can maintain an independent historical existence; such types, the number of which he set at ten, are sharply differentiated and remain absolutely independent of one another. The important thesis of the work is that the last of these types, the Slavic, offers a striking contrast in every conceivable way to the Romance-Germanic type of western Europe. The Slavs are the power of the future; only they are capable of developing a civilization in which the four essential aspects of culture—the religious, spiritual-cultural, political and social-economic—are harmoniously blended. The political hegemony of the Slavs will be achieved with the formation of a pan-Slav federation under the leadership of Russia; the federation would include also a number of non-Slavic east

European nationalities such as the Greeks, Magyars and Rumanians and have its headquarters in Constantinople. Danilevsky's system, marking a break in Slavophile theory with that philosophy of history which conceived of nations as carriers of the universal historical spirit, was favorably received in Russian Slavophile and nationalist circles and by some groups of western and southern Slavs. On the other hand, it was severely criticized by liberal and radical writers, who scored Danilevsky for preaching an unbridled racial egotism.

DANTE ALIGHIERI (1265-1321). Dante's political significance may be viewed under three aspects. First, as a statesman he participated in the public life of Florence between 1295 and 1301. During these years his voice was heard in the councils of the *commune*, of the *popolo* and of the *arti*, and he occupied such varied offices as *prior* for two months in 1300, superintendent of public works and ambassador. Although allied with the Guelphian Bianchi and the family of the Cerchi, Dante belonged to the group of Florentines who strove to curb internal feuds and was conspicuous among those who resisted the efforts of Boniface VIII to extend papal dominion to Florence. The triumph of the pope and the Guelphian Neri in 1301, following the arrival of Charles of Valois, therefore signified Dante's downfall. Sentenced to exile under pain of death he entered upon those wanderings from which he was never to be liberated. Once in the company of other exiles he tried to force his way into Florence; but later he withdrew from the Bianchi, definitely abandoning all political activity. Until his death, however, he continued to cherish hopes—sometimes, as upon the occasion of Henry VII's incursion into Italy, eager and confident hopes—that strife might end in Florence and he might return to his native city.

Judging from the opinions of his contemporaries and from the documents of the time, Dante the statesman was an undistinguished figure fluctuating between corporate and solitary endeavor. Second, as a political ideologist Dante saw the sole salvation for human society in the restoration of the empire. Of all institutions the empire alone, by establishing peace and justice throughout the world wide extent of its power, could initiate earthly happiness; it alone could preserve the church of Rome from corruption and thus assure the spiritual efficiency of that other supreme authority. This ideology, in which can be seen the reflection of Dante's political experience and suffering, took form in the works of his exile, culminating in the *Divina commedia* and receiving doctrinal expression in the *De monarchia*. Since it was in disaccord with actual political trends of the time and ignored the complete decadence of both church and empire in the face of the emerging national states, Dante must be considered under this second aspect as a utopian of no practical significance. Third, as a political philosopher Dante held that divine origin sanctioned the existence of the empire, that is, of the state, no less than of the church. Thus, although only through the erroneous dualistic doctrine of two powers, he gave ethical justification to the history of pagan Rome and ascribed moral worth to civil governments outside the pale of the Catholic church. In this rather unorthodox doctrine may be perceived an unconscious trend toward that progressive liberation which continued to gather force in the Renaissance and the modern world out of the mysticism, the asceticism and the contemplative ideal of the Middle Ages.

But the Dante who has endured as a living force through the centuries of Italian history was neither the statesman nor the political ideologist nor the political philosopher but the man himself, as he was mirrored in his *canzoni* and illumined by the radiance of the *Divina commedia*. Virile, austere, impassioned, uncompromising, receptive to everything lofty, shunning the base and mean, this "disdainful soul," as he once called himself, has been and remains an ideal figure in whom his countrymen have found in their time of trial an example, an inspiration, a comfort and a stern prophet. What all the noblest spirits of Italy have felt Michelangelo thus expressed:

Fuss'io pur lui ch' a tal fortuna nato,
Per l'aspro esilio suo con la virtute
Darei del mondo il più felice stato.

That such an ideal should become distorted into a myth was natural; and later centuries have from time to time attributed to Dante their own multitudinous aspirations. Phrases like "Ah, servile Italy, hostel of grief" (*Purgatorio* VI: 76) and "Ah, Constantine, of how great ill was mother . . . that dowry which the first rich father received from thee" (*Inferno* XIX: 115) have been adopted as watchwords not only against the temporal power of the papacy but in the cause of national unity and independence. At the heart of the Dantean myth as of all myths lies the psychological truth that a moral force possesses infinite power of expansion and lends itself to the performance of all the moral duties which time gradually discloses. Nevertheless, the interpretations given to Dante's words by the diverse parties who have drawn upon his support have impeded and continue to impede a critical estimate of his significance.

The work of restoring the historical truth concerning Dante's political thought was begun in the first half of the nineteenth century by the liberal Catholic or neo-Guelphian historians. Possessing a different conception of the function performed by the papacy and of the struggle between church and empire these historians demonstrated that Dante's Ghibelline ideal ran counter to the course of the history of the commune and therefore of Italian civilization, and would have denied to his own Florence all the commercial, political and artistic eminence which she enjoyed during the two hundred years after his death. Later in the nineteenth century the democrat Carducci exclaimed in a sonnet dedicated to Dante:

Odio il tuo santo impero; e la corona
Divelto con la spada avrai di testa
Al tuo buon Federico in Val d'Olonia.

But such protests as these are still in the realm of political polemics. The best modern criticism confining Dante's political significance within due bounds, has resumed the more fitting task of explaining and interpreting the sublime poem in which his soul lives eternally, not alone for the Italians but for all humanity.

BENEDETTO CROCE

Works: Two authoritative texts of Dante's complete works have been published: *Le opere di Dante Alighieri*, ed. by Edward Moore and P. J. Toynbee (4th ed. Oxford 1924), and *Le opere di Dante: testo critico della società dantesca italiana*, ed. by Michele Barbi and others (Florence 1921). Among the English translations of the *Divina commedia* the best in meter are those by H. N. Cary (ed. by G. Fattorusso,

Florence 1930), and by H. W. Longfellow (ed. by C. Welsh, 4 vols., New York 1909). A standard prose translation is that of C. E. Norton, 3 vols. (new ed. Boston 1920). An edition of the Italian texts by A. J. Butler is accompanied by an excellent English prose version (3 vols., London 1880-92). The best complete translation of the *De monarchia* is by F. J. Church (in Church, R. W., *Dante: an Essay*, London 1878, p. 175-304).

Consult: Dinmore, C. A., *Life of Dante Alighieri* (Boston 1919); Toynbee, P. J., *Dante Alighieri, His Life and Works* (4th ed. London 1910); Grandgent, C. H., *Dante* (New York 1916); Croce, B., *La poesia di Dante* (2nd ed. Bari 1921), tr. by Douglas Ainslie (New York 1922); Church, R. W., *Dante, and Other Essays* (London 1888); Vossler, Karl, *Die göttliche Komödie, Entwicklungsgeschichte und Erklärung*, 2 vols. (Heidelberg 1907-10); Wicksteed, P. H., *Dante and Aquinas*, Jowett Lectures, 1911 (London 1913);

Klaczko, Julian, *Causeries florentines* (Paris 1880); Dunning, W. A., *A History of Political Theories, Ancient and Mediaeval* (New York 1902) p. 230-35; Ercole, Francesco, *Il pensiero politico di Dante*, 2 vols. (Milan 1927-28), and "L'unità politica della nazione italiana e l'impero nel pensiero di Dante" in *Archivio storico italiano*, 75th year, vol. i (1917) 79-144; Gilbert, A. H., *Dante's Conception of Justice*, Duke University publications (Durham, N. C. 1925); *Dante e l'Italia*, published by Fondazione Marco Besso (Rome 1921); Gardner, E. G., *The National Idea in Italian Literature*, Manchester University Lectures, no. xxii (Manchester 1921) p. 1-8; Farinelli, Arturo, *Michelangelo e Dante e altri brevi saggi* (Turin 1918), and *Dante e la Francia, dall'età media al secolo di Voltaire*, 2 vols. (Milan 1908); Hazard, Paul, "Dante et la pensée française" in *La minerve française*, vol. vi (1920) 699-716; Toynbee, P. J., *Dante in English Literature from Chaucer to Cary* (c. 1380-1844) 2 vols. (London 1909).
